ABSTRACT

A TEST OF THE AREA OF REFUGE HYPOTHESIS IN INDO-PACIFIC MARINE BIOGEOGRAPHY

Jonnell C. Sanciangco
Old Dominion University, 2010
Director: Dr. Kent E. Carpenter

Many hypotheses have been proposed to explain the marine biogeographic patterns of species richness of the Indo-Pacific. One of these hypotheses suggests that available habitat area is the main predictor of species richness. This is the basis for the area of refuge hypothesis that attempts to explain the global maxima of species richness found in the Coral Triangle, the area encompassing mostly the Philippines, Indonesia, and Malaysia. This species-area effect also has habitat heterogeneity as a potential component. The purpose of this study is to test the effects of habitat availability predictors, such as shallow water area and coastline length as proxy to area, and the effects of habitat heterogeneity, such as a habitat diversity index and patch density, as predictors of species richness. Problems of analytical scale and centroid location first had to be tested using grids of different sizes (small, medium, large, and Universal Transverse Mercator coordinate system (UTM); with the position of the UTM grid also shifted (UTM_{north/south}, UTM_{east/west}, and (UTM_{northeast/southwest}). An alternative to grid analysis was also tested using 1000, 500, and 100 equal area sections (EAS) of shallow water area to a depth limit of 200m. A total of 7,859 species distribution maps were generated and used to calculate patterns of species diversity. An epicenter of marine biodiversity within the Coral Triangle, in the center of the Philippines and eastern Indonesia is confirmed. The greatest extent of available shallow water habitat area can be found in the Arafura and Sunda shelves, while the highest concentration of coastline length is concentrated in the Philippines and eastern Indonesia. Habitat availability explains more variation in species richness than habitat heterogeneity. The availability and heterogeneity of habitats in the Coral Triangle significantly explains variation in species richness. However, the low regression coefficients associated with these parameters suggests that there are other major factors that contribute to shaping the marine biogeographic pattern of the Coral Triangle.

This thesis is dedicated to Milli and Andre

ACKNOWLEDGMENTS

I would like to thank Dr. Kent Carpenter for all his support and guidance throughout the duration of this thesis and my Master's degree. I would also like to thank my committee members, Dr. John Holsinger and Dr. Hua Liu for their comments and advice. I am also thankful for UNEP-WCMC for providing the shapefiles of coral reefs, seagrass beds, and mangals I used in this study. I am also grateful to Fabio Moretzsohn, Myra K. K. McShane, Gerry Allen, and John McEachran for providing their GIS database I used in creating most of the species distribution maps. Thanks also to Dr. Mark Butler, Dr. N. Rao Chaganty, Dr. Dayanand N. Naik, and Sheth Manasi for their advice in the statistical analyses for this study. I am also grateful to Vineet Katariya, George McLeod, and Peter Etnoyer for their GIS support. I would also like to thank Matt and Sam of ODU Writing Tutorial Services for their insightful reviews. Thanks also to the GMSA team and to all the Carpenter Lab people. I am indebted to my parents, in-laws, and friends for their unending support and encouragement. I also want to thank Milli and Andre for believing in me through all these years. You both are my inspiration. My Masters program was funded by Tom Haas and the New Hampshire Charitable Foundation through the International Union for Conservation of Nature, Global Marine Species Assessment (IUCN, GMSA) project at Old Dominion University.

INTRODUCTION

No other topic in marine biogeography has had more attention in the literature than the origins of the epicenter of marine biodiversity of the Indo-Pacific. This epicenter, the so-called Coral Triangle, encompasses much of Indonesia, Malaysia, the Philippines, Papua New Guinea, the Solomon Islands, Timor-Leste, and Brunei (Fig. 1). Numerous hypotheses have been put forward to explain this well-known biogeographic pattern (Rosen, 1988; Bellwood & Wainwright, 2002). One of these hypotheses, the area of refuge hypothesis (McCoy & Heck, 1960), correlates with one of the paradigms of ecology, that larger areas contain more species (Rosenzweig, 1995). Potentially correlated with this species-area relationship and the area of refuge hypothesis is the notion that greater habitat heterogeneity can support greater diversity of species (MacArthur & Wilson, 1967; Rosenzweig, 1995, Tews *et al.*, 2004; Hoeksema, 2007; Báldi, 2008). Extent and diversity of habitat has been used as a major factor explaining shifting patterns of marine biodiversity through geological time (Renema, *et al.*, 2008). The Coral Triangle currently has the greatest concentration of tropical shallow water habitat on earth, encompassing highly diverse and extensive areas of coral reefs, mangals, seagrass beds, estuaries, and soft sediment habitat (Woodland, 1990; Carpenter, 1998; Randall, 1998; Carpenter & Springer, 2005). This extent and diversity of habitat appears to correspond closely with species-area and species-habitat diversity relationships for this region. However, other explanations for the peak of diversity in the Coral Triangle are more hotly debated. For example, this area is considered an area of origin where speciation events have frequently occurred (Ekman, 1953; Briggs, 2000). The area has also been considered an area where species arose peripherally and have accumulated through prevailing currents (Ladd, 1960; Rosen, 1988; Jokiel & Martinelli, 1992), through island integration (Carpenter & Springer, 2005), or through supporting species survivorships (Barber & Bellwood, 2005). It has also been hypothesized that the Coral Triangle is mostly an area of overlap between Indian and Pacific Ocean biotas (Kay, 1980; Woodland, 1983; Wallace *et al.*, 2000). Others claim that no single explanation adequately accounts for the peak of biodiversity in the Coral Triangle but that a combination of factors best explains this pattern (Palumbi, 1996; Wallace, 1997; Carpenter, 1998; Randall, 1998; Wilson & Rosen, 1998; Allen & Adrim, 2003; Carpenter & Springer, 2005). The purpose of this thesis is to test hypotheses of species-area relationships of marine shore biota in the Indo-Pacific region. How

much variation in species richness is explained by the availability of habitat area? Does habitat area account for much or all of the variation explained in species richness in the Indo-Pacific region, or are there other factors responsible? Does heterogeneity of habitat affect species richness, and how does this effect compare to area effects? Hypotheses relating to these questions will be tested using generalized species distributions and habitat area information, using a Geographical Information System (GIS).

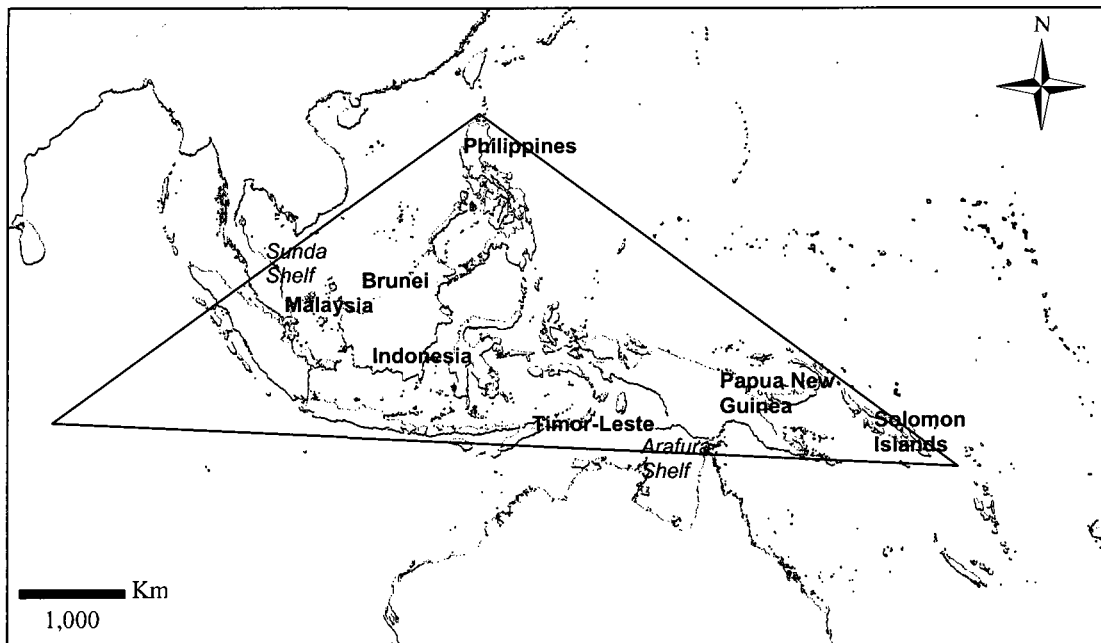

Figure 1 The Coral Triangle, considered as the area of highest marine diversity in the world.

Understanding uneven spatial patterns of biodiversity across the planet is central to biogeography (Gaston, 2000). Confounding this understanding is the basic observation that larger areas contain more species (Rosenzweig, 1995). Teasing out ecological, evolutionary, and geographical effects when comparing species richness in areas of different sizes must take this effect into account. Species-area relationships were originally studied to determine optimal sample size and number, to determine the minimum area of a “community”, and to estimate the number of species in areas much larger than the sampled region (Connor & McCoy, 1979; Rosenzweig, 1995). This method of predicting the number of species led to the formulation of mathematical models describing species-area relationships. Among the principal functions used

include the power model (Arrhenius, 1921) and exponential model (Gleason, 1922), both of which have been the focus of biological interpretation that lead to two alternative explanations of the effects of area on species richness. MacArthur & Wilson (1963, 1967) expounded Preston's (1960, 1962) power function model as a prediction of the theory of island biogeography. This hypothesis states that species number is a function of a dynamic equilibrium between immigration and extinction rates moderated by population sizes. Larger areas support more individuals in a population, and therefore, populations are less likely to go extinct from chance events. Larger populations also generally contain more genetic variation and are more likely to adapt to changing environmental conditions. This hypothesis is referred to as the area *per se* hypothesis and does not directly take into consideration the importance of habitat diversity (Kallimanis *et al.*, 2008).

Conversely, Williams' (1964) habitat-diversity hypothesis was derived from the exponential model, which proposes that as the amount of area sampled is increased, new habitats with their associated species are encountered and consequently the species number will increase. Other factors such as the influence of time in species richness (Adler & Lauenroth, 2003), energy available for productivity (Storch *et al.*, 2005), or chance events (Gaston, 2000) have been proposed as important in species-area relationships, but Rosenzweig (1995), Tews *et al.* (2004), and Báldi (2008) consider habitat heterogeneity as the vital factor in determining species richness. More varieties of habitat offer greater availability of resources that can support larger populations and reduce the probability of extinction due to chance events (Shaffer, 1981). The role of habitat heterogeneity is also acknowledged by the proponents of equilibrium theory, noting that area and habitat heterogeneity are usually positively correlated, which also leads to confounding influences on species richness (MacArthur & Wilson, 1967; Rosenzweig, 1995; Báldi, 2008).

The Indo-Pacific is considered the most biologically diverse marine region worldwide, encompassing an array of marine ecosystems including coral reefs, mangrove forests, seagrass beds, seaweed beds, and soft-bottom communities. The Indo-Pacific is also the largest marine biogeographic realm, with shelf waters extending longitudinally more than halfway around the world and through more than 60° of latitude (Briggs, 1999). It is a tropical and subtropical region extending from the Indian Ocean (including the Red Sea and Persian Gulf) eastward to the central Pacific Ocean through Polynesia to Easter Island (Spalding *et al.*, 2007). The extent of shallow water area in the Indo-Pacific is a result of a complex geological history in the region. During the early Jurassic, about 180 million years ago (MYA), initial rifting of Gondwanaland occurred, causing the separation of Africa and South America and opening up of the Atlantic (Lomolino *et al.*, 2006). Extensive sea floor spreading continued to occur among the remaining parts of the

Gondwanaland throughout the Cretaceous period (65 to 2 MYA), which lead to the closing of the circum-equatorial Tethys Sea, creating a separation between the Atlantic and Indo-Pacific oceans as Africa and Eurasia collided. During the period of the closure of the Tethys Sea, three separate successive biodiversity hotspots (areas of exceptional species richness) developed coinciding with areas of tectonic collision (Renema *et al.*, 2008). These areas roughly coincide with present day Mediterranean, the Arabian-Eurasian area, and the Indo-Australian interface. This tectonic activity both created and maintained extensive and complex shallow-water habitat at different periods. The most recent of these collision areas and the current biodiversity hotspot is the Coral Triangle (also sometimes referred to as the Indo-Malay Philippine Archipelago or Indo-Australian Archipelago). Occurrences of marine species throughout the Indo-Pacific have been well documented (Rosen, 1971, 1988a; Valentine, 1973; Springer, 1982; Kay & Palumbi, 1987; Kohn & Perron, 1994; Veron, 1995; Palumbi, 1997; Burke *et al.*, 2002). Species richness in the Indo-Pacific is negatively correlated with the distance from the Coral Triangle (Nishida & Lucas, 1988; Palumbi, 1997; Briggs, 1999).

A wide variety of hypotheses have been proposed to explain the peak in concentration of marine species in the Coral Triangle (Carpenter & Springer, 2005; Bellwood & Meyer, 2009), six of which are largely interconnected. These have been summarized as center of origin, area of overlap, area of accumulation, area of refuge hypotheses (Carpenter & Springer, 2005), center of survival (Barber & Bellwood, 2005), and an eclectic hypothesis (Palumbi, 1996; Wallace, 1997; Carpenter, 1998; Randall, 1998; Wilson & Rosen, 1998; Allen & Adrim, 2003; Carpenter & Springer, 2005). The center of origin hypothesis assumes that the Coral Triangle was an area of intense speciation events and that the negative correlation of species richness from the Coral Triangle is a result of attenuating dispersal from the center (Ekman, 1953; Briggs, 2000; Mora *et al.*, 2003). The area of overlap hypothesis assumes the area is a mixing of Indian Ocean and Pacific Ocean biotas that differentiated primarily because of Pleistocene vicariant events that separated these biotas (Kay, 1980; Woodland, 1983; Bellwood & Wainwright, 2002). The center of origin and area of overlap hypotheses are similar in that they both assume this region has been an area of intense lineage diversification. The center of accumulation hypothesis assumes that most speciation events occurred outside the Coral Triangle and that species dispersed into and accumulated in the Coral Triangle (Ladd, 1960; Rosen, 1988; Jokiel & Martinelli, 1992). The center of survival hypothesis is similar to the center of accumulation model, although diversification can occur anywhere, not only in peripheral habitats (Barber & Bellwood, 2005). The area of refuge hypothesis does not assume where speciation has occurred but that the concentration of species is primarily a function of available habitat (McCoy & Heck, 1976;

Bellwood & Hughes, 2001). The Coral Triangle represents the largest tropical shallow water habitat on earth (Woodland, 1990; Carpenter, 1998) with the greatest diversity of habitat types (Hoeksema, 2007) and the epicenter is a function of a species-area relationship. A seventh basic hypothesis category exists to explain the Coral Triangle biodiversity epicenter: the mid-domain effect (Colwell & Lees, 2000; Connolly *et al.*, 2003; Bellwood *et al.*, 2005). This is a null model that assumes no ecological or evolutionary effects but instead, that a random placement of distributions will show most overlap in the center of the region because of the size of distributions and boundaries of the region. Bellwood & Hughes (2001) conclude that mid-domain effects on coral reefs are relatively minor compared with the overriding influence of habitat area because of the relatively high diversity assemblages in the western Indian Ocean.

The center of origin, area of overlap, center of accumulation, and center of survival hypotheses all relate, to some extent, to the area of refuge hypothesis in that available habitat is needed to both maintain and allow accumulation of biodiversity. Despite its central importance to these hypotheses, tests of area of refuge effects on biodiversity in the Indo-Pacific have been constrained by a limited haphazard selection of taxa and geographic survey sites (Bellwood & Hughes, 2001; Bellwood *et al.*, 2005). These studies looked at the mid-domain effect, and latitude, longitude and habitat area but did not consider habitat heterogeneity. Habitat area was the most important factor in explaining species richness (Bellwood & Hughes, 2001; Bellwood *et al.*, 2005).

The primary purpose of this thesis is to test the area of refuge hypothesis with regards to available habitat and habitat heterogeneity. This thesis will test specific hypotheses to determine the amount of variation explained by habitat area and habitat heterogeneity in the Indo-Pacific using species distribution maps of fishes and invertebrates, and habitat maps of coral reefs, seagrass beds, and mangals using GIS. GIS is commonly used in spatial analyses (Swenson, 2008), habitat prediction and modeling (Ray *et al.*, 2002; Wilkin *et al.*, 2007), and mapping spatial distributions for species conservation status assessment (Carpenter *et al.*, 2008). Mapped classifications of patterns in biodiversity have long been considered an important tool in evolutionary studies and conservation planning, which, unfortunately, has largely been restricted to terrestrial studies (Spalding *et al.*, 2007). Complete GIS datasets are only available for most terrestrial species, including mammals and birds of the world, North American tree species, and global amphibian species (Swenson, 2008). Swenson (2008) discussed and summarized the use and influence of GIS in niche modeling and in evolutionary biology research studies for land snails, grasshoppers, and crickets. GIS analyses and modeling were also done for invasive plants in California (Dark, 2004), beetles of the subgenus *Anisodactylus* (Noonan, 1999), South

American pocket mice (Anderson *et al.*, 2002), and kangaroos (Skidmore *et al.*, 1996). Recently, some studies have shown how GIS applications can be used in marine management program (Friedlander *et al.*, 2007; Clark *et al.*, 2003), but the methods are used in smaller scale compared to the whole Indo-Pacific region. The use of GIS in marine ecosystem has also been restricted by the lack of distribution range maps in GIS file formats. There are, however, a few studies that use GIS in studying the distribution patterns of marine species at a larger scale (Moretzsohn & McShane, 2004; Bellwood *et al.*, 2005; Allen, 2007) but their mapping methods mostly involved using point distribution data, or drawing a minimum-bounding polygon that encompasses all the georeferenced points of the species location. Using point data is useful in conservative biology studies but does not include all localities where a species is potentially found. Similarly, the minimum-bounding polygon often produces a map stretching across areas that are uninhabitable, such as open ocean where coastal species do not occur. This study uses standardized basemaps that take these limitations into account.

This study not only intends to focus on answering biogeographic questions but also to contribute to the field of marine GIS. These contributions include the creation of an extensive GIS database of the world's shore species, which can be used and customized to test further biogeographic studies. This thesis also used GIS tools to test large scale studies, which has not been previously conducted. The use of GIS in the marine sciences is currently developing. Many disciplines, such as marine biology, geology, and conservation are incorporating GIS-based research into their systems (Bremen, 2002). Internationally, there is a growing trend towards adopting a marine GIS in terms of data access and exchange, spatial and temporal representation, and the need for more temporally dynamic analytical models that incorporate the principles of biodiversity conservation in the management of aquatic resources (Wright & Halpin, 2005). The need to identify heterogeneity within and distinctiveness between marine ecosystems can greatly increase the effectiveness of conservation planning. The Indo-Pacific region has become one of the world's top priorities for marine conservation not only because of its high biodiversity but also because it has the most threatened marine ecosystems (Bryant *et al.*, 1998; Roberts *et al.*, 2002; Burke *et al.*, 2002; Carpenter & Springer, 2005).

METHODOLOGY

The application of GIS methodology to marine biogeographic questions is still being developed. The methods in this study are largely novel or adaptations from terrestrial literature. Therefore, the methods themselves needed to be tested before the hypothesis could be tested. This study used ArcView 3.3 and ArcGIS 9.3 (Environmental Systems Research Institute) to generate species distribution maps, process existing GIS maps, and analyze spatial data. Most datasets used in this study exceeded the maximum limit of 2GB in ArcGIS. Therefore, datasets were often analyzed first in subsets and then subset results were combined for a final analysis.

Spatial Range

The study range covers the entire Indian Ocean (including Red Sea and Persian Gulf) and the entire Pacific Ocean within the latitudinal limit of 30°N to 30°S. All data layers were projected onto the World Cylindrical Equal Area coordinate system centered at 130° longitude.

Species Distributions and Basemap

Generalized distributions of species were obtained from a number of different sources. Pre-existing GIS databases existed for marine invertebrates and coral reef fishes (Veron, 2000; Moretzsohn & McShane, 2004; Allen, 2007). For non-coral reef fishes, distribution information was collected from scientific articles (Trewavas, 1977; Vari, 1978; Masuda *et al.*, 1984; Heemstra, 1986; Starnes, 1988; Sasaki & Amaoka, 1989; Sasaki, 1990, 1994, 1995, 1999; Talwar & Jhingran, 1991; Yamashita & Kimura, 2001; Iwatsuki *et al.*, 2006), Food and Agriculture Organization field guides and species' catalogues (Fischer & Whitehead, 1974; Collette & Nauen, 1983; Fischer *et al.*, 1984; Russell, 1990; Bianchi *et al.*, 1993; Heemstra & Randall, 1993; Carpenter & Niem, 1998; Compagno, 2002; Compagno *et al.*, 2005), and an internet database (Robertson & Allen, 2008). Distributions of mangroves and seagrasses were taken from atlases (Spalding *et al.*, 1997; Green & Short, 2003). Many of the maps were checked for accuracy and additional ones developed by experts as part of the International Union for Conservation of Nature, Global Marine Species Assessment (Carpenter *et al.*, 2008). In particular, distributions of reef-building corals, mangroves, seagrasses, and several families of coral-reef fishes were checked and further developed in this manner. The total number of species maps produced in this study is 7,859 (Appendix 1), of which 1,212 are invertebrates (crustaceans and molluscs), 5,708 are fishes, and 939 total maps are for habitat-forming species, i.e. corals (820), seagrasses (50), and mangroves (69).

Three different types of species distribution basemaps were used in this study dependent on the ecology of the species and the need to analyze and visualize distributions. The emphasis in this study is to test biogeographic hypotheses relating to marine species found primarily over continental or island shelves. The depth limit of these shallow-water species is typically set at 200m (Valentine, 1971). Marine species that inhabit this shallow water ecosystem are pelagic, benthic, or demersal. Pelagic species typically range widely and are found not only over shallow water but many also range over open ocean. A generalized distribution encompassing the entire range, including open ocean was adopted for those oceanic species that are also found over shallow water (Fig. 2a). Benthic species that are attached or crawl over the ocean floor and demersal species that swim close to the bottom are more restricted to shallow water. For all these nearshore shallow water species, the 200m bathymetry was adopted as the basemap (Fig. 2b), regardless of the actual depth limits of the species. All tests of hypotheses were carried out using distributions based on this 'bathymetry basemap', including pelagic species' distributions that were cut to this basemap for analyses.

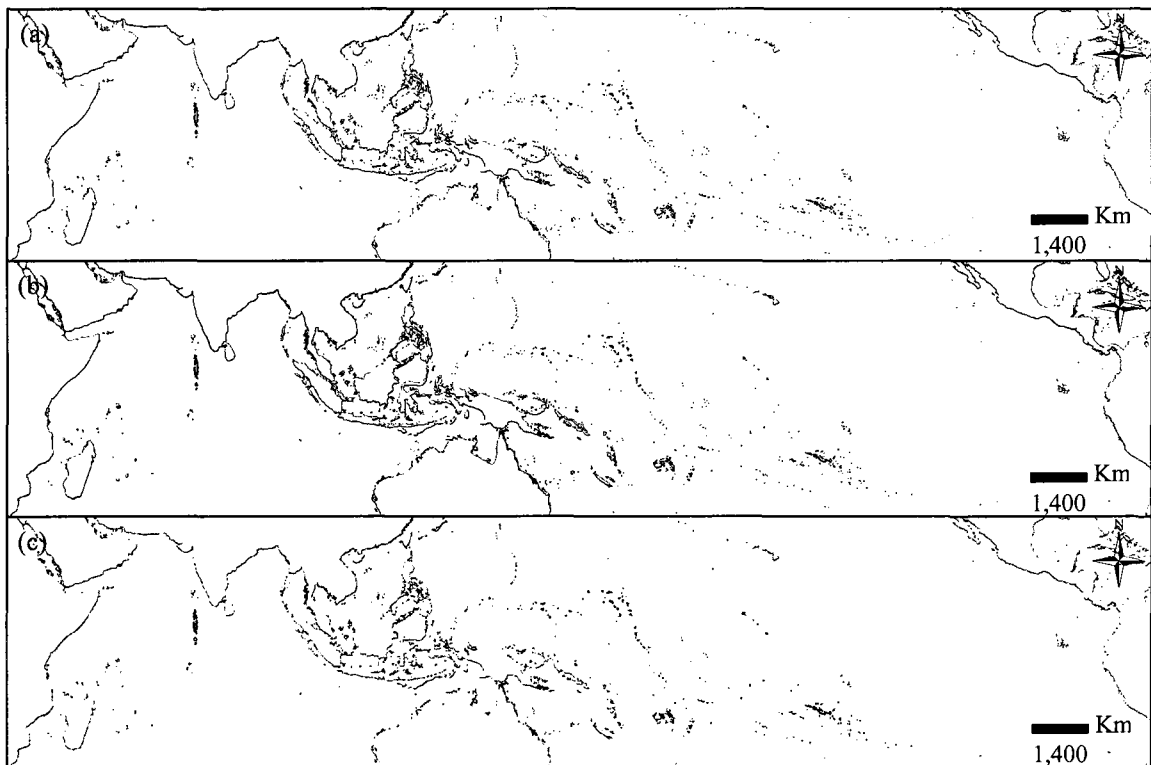

Figure 2 Three types of maps used in the study: (a) Sample of pelagic species map (*Manta birostris*); (b) Bathymetry basemap; (c) Visualization basemap.

A third type of basemap was developed primarily to help visualize patterns of biodiversity. This was necessary because the 200m bathymetry often occurs close to shore (Fig. 2b), and at the scale of the Indo-Pacific, these areas become nearly invisible in illustrations. Therefore, a 'visualization basemap' was adopted made up of the 200m bathymetry in union with the 100km buffer from the shore (Fig. 2c). All benthic and demersal species' distributions were first created using this visualization basemap and then cut to the bathymetry basemap for purposes of analyses. All shapefiles were drawn using ArcView 3.3. For each species, a polygon representing the extent of distribution was drawn over the basemap, and this was used to cut the basemap for the final distribution map. ArcView scripts were used to automatically name shapefiles in the attribute table. The final species distribution map was converted into rasters of 10km by 10km cell size by using a script in ArcView 3.3 to visualize biodiversity patterns.

Habitat Area Layers

Habitat heterogeneity was calculated from shapefiles representing area values for coral reef, seagrass bed, mangal (mangrove swamp), and soft-bottom habitats. Three of the habitat shapefiles (i.e. coral reefs, seagrasses beds, and mangals) were used in this study with permission from the United Nations Environment Programme - World Conservation Monitoring Centre (UNEP-WCMC) and originated from the global marine habitat atlas projects (Spalding *et al.*, 1997; Spalding *et al.*, 2001; Green & Short, 2003). The fourth habitat, soft-bottom, was generated from a 200m bathymetry layer processed from ETOPO1 (National Geophysics Data Center) raster data (Amante & Eakins, 2008). Soft-bottom was defined as the area within the 200m bathymetry that did not contain coral reef, seagrass beds, or mangals. The non-soft-bottom habitat shapefiles were produced at different times using different methods and therefore required some standardization. The habitat layers were overlaid to determine where overlap occurred. When overlap did occur, average size of polygons and general understanding about the biology of the habitat type was used to decide which habitat type took precedence. Mangal polygons were generally smallest, so if overlap occurred with seagrass or coral reef habitat types, the other habitat types were cut to conform to the maximum size of the mangal habitat. Coral reef polygons were generally smaller than seagrass bed polygons, and therefore, coral reef polygons were cut from seagrass bed polygons. This is consistent with the fact that coral reefs are often interspersed within seagrass beds and adjacent to mangals.

Land areas were erased from marine habitat data layers using World Vector Shoreline data. This data, a standard product of US Defense Mapping Agency, is a digital data file at a nominal scale of 1:250,000, containing the shorelines, international boundaries and country

names of the world (Soluri & Woodson, 1990). The World Vector Shoreline was also used to generate the coastline length by converting this to a line using conversion tools in ArcGIS 9.3. Coastline length was used here as a proxy for available nearshore habitat. A more complex shoreline can be considered a “larger area” compared to a simpler coast. This method was first employed by Etnoyer (2001) who defined it as “shoreline complexity”.

Raster Analysis

The overlay raster tool in ArcGIS 9.3 was used to combine all the rasterized species distribution maps (maps drawn using the visualization basemap; Fig. 2c). This tool assigns a value for each cell that corresponds to the number of species found within that cell. Thus, higher values correspond to a higher number of species and lower values have lower species richness. Biodiversity ‘hotspots’ were identified using this overlay.

Fishnet Grids, UTM Grids, and Equal Area Sections

Species-area studies typically use superimposed cells to investigate the correlation of species richness with other variables. Here, two types of cells were used – grids and equal area sections. Grids are often used when collecting data over large areas of earth, such as in this study. There are four elements that describe a grid: the map projection, the number of columns and rows, the numbers of grid cells per map unit, and the grid cell that corresponds to the map origin. Grids are an efficient means of storing data because the location of a value within the grid is implicit and constant, allowing easy comparison among data points (Maling, 1992). The study area was divided into grids of different sizes to test if the size of the grid has an influence on the species-area relationship and if the commonly used Universal Transverse Mercator coordinate system (UTM) grid has any bias compared to using other grid sizes. The UTM is a grid-based system composed of 60 different zones (with each grid measuring $\sim 616,995 \text{ km}^2$, except for grids located along the extent of study range which cover less area), each of which was anchored in a specific secant transverse Mercator projection (Snyder, 1987). Map projections are specified as a set of equations giving x and y in terms of latitude and longitude. There is no best map projection, and each projection has its own use based on different properties – the two most important are whether they are conformal or equal-area. Most projections have only one of the two, and some have none at all (Maling, 1992). The UTM system is predisposed to distortion in area and distance. Therefore, three different fishnet grid sizes; small ($23,021 \text{ km}^2$), medium ($92,084 \text{ km}^2$), and large ($368,337 \text{ km}^2$), encompassing the whole study area, were generated to facilitate evaluation of different scales using the ‘create fishnet’ function in ArcGIS 9.3 and to

compare with UTM (Fig. 3). In addition, UTM projection was moved about halfway up ($UTM_{north/south}$), sideways ($UTM_{east/west}$), and diagonally ($UTM_{northeast/southwest}$) to determine if the location of the UTM centroids can influence the result of the analysis. Some of the grids fall along the coastal areas and include land. This produces variable effective grid size in terms of available shallow water habitat and is a fundamental flaw with grids that has been dealt with in several ways, one of which is to combine adjacent grids (Currie, 1991; Badgley & Fox, 2000; Hawkins *et al.*, 2003b; Diniz-Filho *et al.*, 2004; Nogués-Bravo & Araújo, 2006). Grids that contain nearly all land were removed from the analysis (these contained 85 to 99% of land) while others were combined with adjacent grids to obtain water areas approximately equal to a single grid with 100% water (Hawkins *et al.*, 2003b; Bini *et al.*, 2004).

Equal area sections of shallow habitat were generated to isolate the effects of area on shore species richness from the effects of habitat diversity. Grids have varying shallow water area and therefore cannot account for this. The species tested in this study are coastal species and therefore the 200m bathymetry shapefile of the Indo-Pacific region was partitioned into three sets of equal area sections using a theme partition script (Huber, 2000) in ArcView 3.3. This script worked by recursively dividing the polygon until a user-specified number of equal-area sections was created. Four different equal area partitions were chosen to compare the effect of different portion sizes: 1000 equal area sections (each section $\sim 8,144 \text{ km}^2$), 500 equal area sections (each section $\sim 16,287 \text{ km}^2$), 100 equal area sections (each section $\sim 81,434 \text{ km}^2$), and an alternative 100 equal area sections designated as 100b (Fig. 4). The 100b partition was created in two steps: first, by dividing the shallow water into two equal sections, then dividing each section into 50 equal partitions. This method changed the orientation of how the different sections were cut to test if orientation had a significant effect on species richness correlations – in a way similar to changing the centroid location using grids.

Several functions and tools in ArcGIS 9.3 were used to create the final sets of maps that were used to test relationships between the habitat layers and patterns of species richness. The ‘calculate geometry function’ was used to compute coastal length and shallow water (area within the 200m depth contour), coral reef, mangal, seagrass, mangrove, and soft-bottom area per grid or equal area section. Merge, dissolve, clip, erase, and frequency tools were used to calculate the number of species present in each grid and equal area section. Therefore, each grid unit or equal area section had a corresponding area measurement of each habitat and coastal length, and the number of all species present. These attributes were exported into a Microsoft Excel spreadsheet (Appendix 2 & 3) where patch density and the habitat diversity index (see below) were then

calculated. This matrix of species richness and habitat area values was imported into SPSS ver. 16.0 (SPSS Inc.) for Poisson regression and other statistical analyses.

Data Classification

Grids were further classified into three different types based on their location – coastal, offshore, and oceanic (see Appendix 2). Coastal grids were defined as the grids touching the coastline of the mainland or continent. Offshore grids were the grids that do not touch the mainland coast, but were found within the 200m bathymetry. Oceanic grids were assigned to those grids that fall in the oceanic islands. Grids were also divided into two biogeographic regions – Indo-West Pacific (IWP) and Eastern Tropical Pacific (ETP) (see Appendix 2).

In order to visualize how shallow water area and coastal length were distributed in the Indo-Pacific, data matrices derived from grids were classified according to the assigned values of shallow water area and coastal length. Data classification was performed by grouping similar features into classes and assigning the same symbol to each member of the class. Here, shallow water area and coastal length were classified into equal intervals of 10 classes, such that each class represents a 10% increase or decrease of values. Grids belonging to the first class, therefore, had the highest available shallow water area and coastal length, respectively. Locations of the highest available habitat were then compared using shallow water area and coastal length.

Partitions Using Modified Large Marine Ecosystems (LMEs)

Large Marine Ecosystems (LMEs) were developed by NOAA for ecosystem based management purposes. LMEs were defined as large areas of ocean space that are adjacent to the continents in coastal waters where primary productivity is generally higher than in open ocean areas (Sherman & Hempel, 2009). In this study, LMEs were used to divide the study range and to investigate the different parameters that affect species richness. The original LME boundary polygons (NOAA Fisheries), however, do not coincide with the datasets used in this study. These polygons did not cover some of the locations and did not match the coastline used in this study. To address these issues, a modified LME shapefile was created by drawing additional polygons or extending the original LME polygons, to cover the areas that were not previously covered (Fig. 5). The modified LME shapefiles were then used to identify features in overlay analysis to determine the species-area and species-habitat correlations per LME region.

Calculating Measures of Habitat Heterogeneity

Two functions of habitat heterogeneity were evaluated in this study: patch density and a habitat diversity index. Patch density, a measure of spatial heterogeneity, is one method to quantify landscape structures by counting the number of patches in an area (Li & Reynolds, 1993). The density of patches could serve as a good heterogeneity index because a landscape with greater patch density would have more spatial heterogeneity (McGarigal & Marks, 1995). The other measure of heterogeneity used in this study involves a modification of the Shannon-Weiner diversity index (Shannon & Weaver, 1963). Most heterogeneity measurements that use diversity indices are classified as ‘structural diversity’, are usually based on multiple study sites, and are usually most appropriate for studies that require ‘subareas’ of different structural groups for species to persist in the study area (Magurran, 1988; Tews *et al.*, 2004). In this study, the habitat diversity index is the measurement used to compare diversity between habitat samples or ‘subareas’ such as the coral reefs, seagrass beds, mangal, and soft-bottom of the Indo-Pacific region.

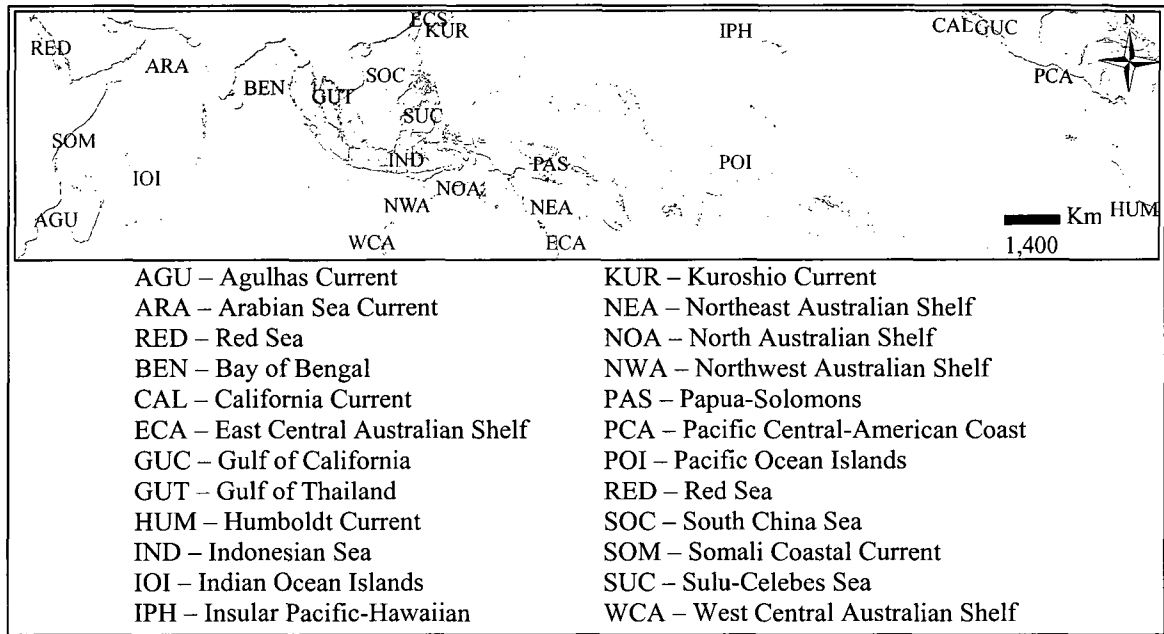

Figure 5 LME feature layers used in the study modified from the LME polygon boundaries (NOAA).

Habitat heterogeneity indices were calculated from the matrix of species richness and habitat area values per grid unit and equal area section. These measures of habitat heterogeneity included patch density and habitat diversity index. Patch density was counted as the total number of individual polygons of corals, seagrasses, mangroves, and soft-bottom shapefiles within the 200m bathymetry layers per grid unit or equal area section. Coral reef, seagrass bed, and mangrove forest are composed of multiple independent polygons (i.e. patches) while the patches for soft-bottom 200m bathymetry is a result of converting raster images into vector in ArcGIS 9.3. The formula for patch density was computed as:

$$PD = \left(\frac{\text{No. of patches (polygons)}}{\text{Shallow water area (km}^2\text{)}} \right) \times 100 \text{ (convert to hectares)}$$

The habitat diversity index was calculated from the values of the total area for each habitat (coral reefs, seagrass beds, mangrove forests and soft-bottom) for each grid unit and equal area section. The Shannon-Weiner Information Theory formula (Shannon & Weaver, 1963) was given as:

$$H = -\sum p_i \ln p_i \quad \text{or}$$

$$H = -\sum (n_i/N) \ln (n_i/N)$$

where n_i = area for each habitat and N = total habitat area.

Species Curves and Statistical Methods

The data matrices that include species richness, habitat areas, and the habitat heterogeneity indices per grid unit, equal area section, and modified LME region were used to calculate species area-curves and to complete other statistical analyses. Poisson regression was used because richness is often considered as a form of count data; hence, the data should be plotted using the log of the response variable. Grids and equal area sections with zero values for the species richness, shallow water area, coastline length, and patch density are removed from statistical analyses. Zero values of habitat diversity index, however, means that only one habitat type is found in a certain cell. Thus, values for this heterogeneity index were transformed by adding 0.5 to the value. The log of species richness for fishes, invertebrates, and habitat-forming species (S) was used to compute four species-area curves: (1) log S vs. shallow water area; (2) log S vs. coastal length; (3) log S vs. habitats' patch density; and (4) log S vs. habitat diversity index of the entire Indo-Pacific region. Species-area curves 1 and 2 were assigned as habitat availability indices, while species-area curves 3 and 4 were treated as measures of habitat heterogeneity. All curves were also calculated for data matrices from equal area sections and modified LME regions, except for 1 and 2 in equal area sections, because of the constant shallow water area variable. Statistical significance of these relationships was tested in SPSS 16.0.

RESULTS

Species richness across the Indo-Pacific shows the expected pattern of highest richness in the Coral Triangle, in an analysis from the combined rasterized data (10km x 10km grid) of 7,859 distribution maps (Fig. 6a). The central Philippines has the highest 2.5% of species richness, and the highest 10% is found in most of the Philippines and eastern Indonesia (Fig. 6b). About 36% of all species in this study are found in the north and central part of the Coral Triangle. Separate analyses of all fishes, coral reef fishes, molluscs and crustaceans, and the habitat-forming species (corals, mangroves, and seagrasses) each show a similar peak of species richness in the Coral Triangle (Fig. 7). The pattern of fishes species richness (all fishes and just coral reef fishes) is most similar to the combined analysis (Figs. 7a & b) while molluscs and crustaceans are most concentrated in the northern part of the Coral Triangle (Fig. 7c). The highest 10% of species richness of corals, mangroves, and seagrasses is widely distributed throughout the Coral Triangle, with the highest 2.5% in the northern and central part (Fig. 7d). The top 1% with the greatest amount of species richness is found in the central Visayas (Fig. 6c). The areas of least species richness in the combined analysis are in the eastern Pacific and along parts of the northern coasts of the Indian Ocean (Fig. 6a). The low species richness in the open ocean represents the pelagic species such as *Katsuwonus pelamis* (skipjack tuna), *Manta birostris* (manta ray), and *Rhincodon typus* (whale shark) that are also found over coastal waters.

Concentration of shallow water area and coastal length in the Indo-Pacific appears unevenly distributed using fishnets and UTM grids as a basis for classifying the available habitats. In all grid sizes, most of the cells belong to the class having the lowest amount of available habitat (Table 1, blue) and very few cells are included in the class with the highest amount of available habitat (Table 1, red). The cells that belong to the classes with relatively high values of shallow water and coastal length (Table 1, yellow to red) are mostly located within or near the Coral Triangle (Figs. 8 & 9).

Figure 6 Overlay of raster data produced from 7,859 species distribution maps. Each change in shade represents an increase or decrease of 70 species (40 total classes or a 2.5% change per class). (a) Pattern of species distribution in the entire Indo-Pacific region. The top 10% for the highest species richness is found in the Coral Triangle (marked in black, with decreasing increments of species richness indicated by lighter shades), and the remaining decreasing increments of species richness are indicated by lightest shades of gray; (b) The top 10% of concentration of species is in the Coral Triangle, with Philippines as the epicenter, represented by four different shades of black. The greatest diversity is darkest shade (2,761 to 2,831 species), followed by dark shade (2,691 to 2,760 species), light shade (2,620 to 2,690) and lighter shade (2,549 to 2,619 species); (c) The top 1% of species (2,804 to 2,831 species) are found within the Visayas in central Philippines (black).

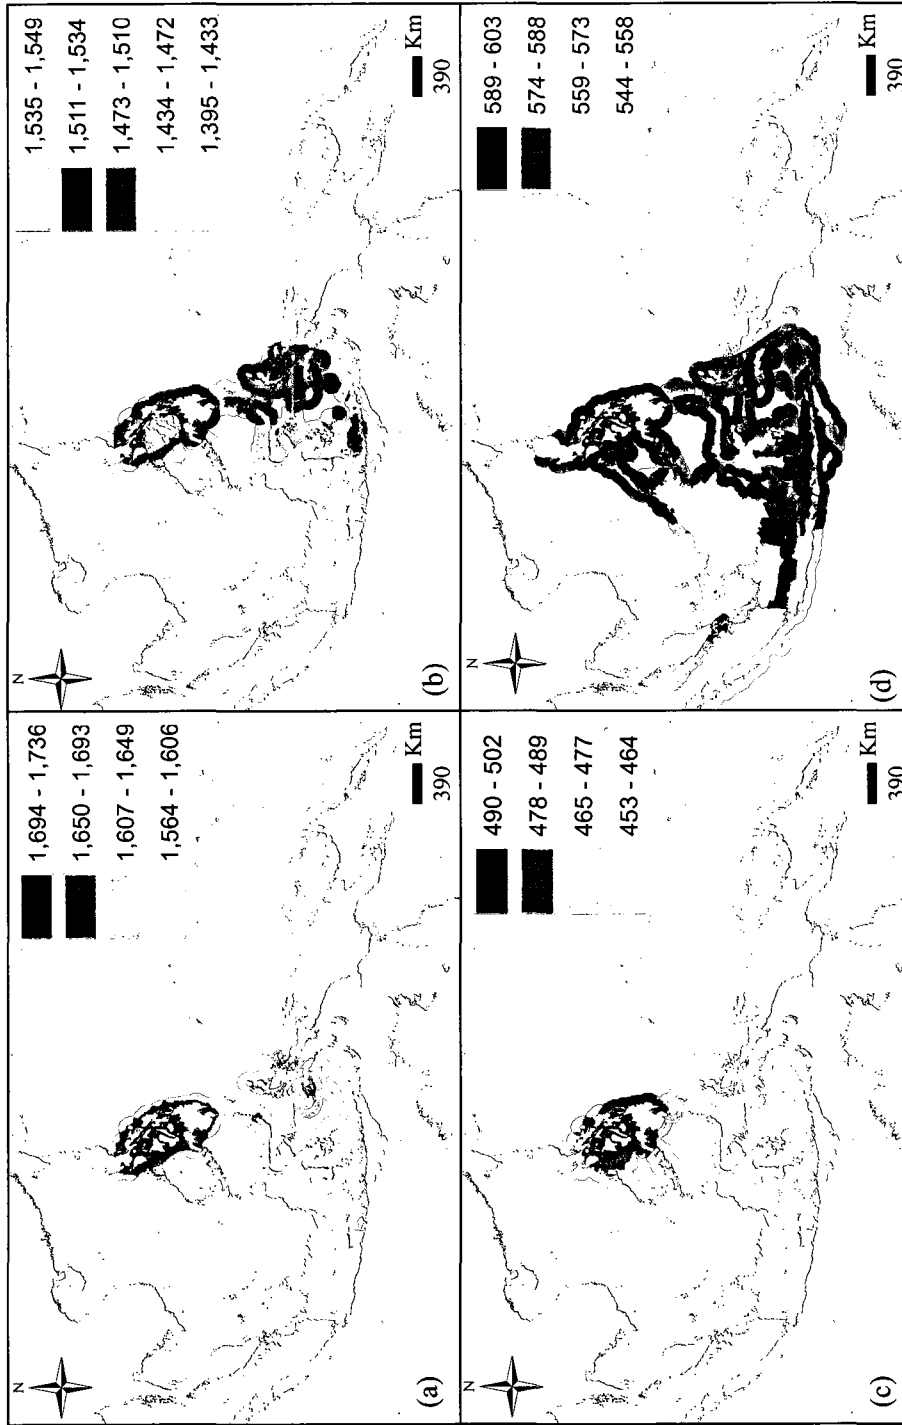

Figure 7 Pattern of species diversity in the Coral Triangle for each species group. Each change in shade represents an increase or decrease of 2.5% per class. The numbers indicate the total number of species belonging to the top 10% of species richness (shades in black) for each species group. (a) All fishes; (b) Coral reef fishes showing the top 1% of species richness (white in the middle of black shades); (c) Molluscs and crustaceans; (d) Habitat-forming species (corals, seagrasses, and mangroves).

Table 1 Number of cells belonging to each class after classifying the grids into 10 classes. Each class represents a 10% increase or decrease of values of shallow water area (SW) and coastal length (CL). Cells assigned to the first class (white) registered the lowest amount of shallow water area and coastal length, while cells in the 10th class (black) have the greatest extent of shallow water area and coastal length. Cells that registered zero values are not included in the classification. The pattern for each class corresponds to legends in Figs. 8 & 9.

Class	Small		Medium		Large		UTM		UTM _{n/s}		UTM _{e/w}		UTM _{ne/sw}

Fig. 9 continued

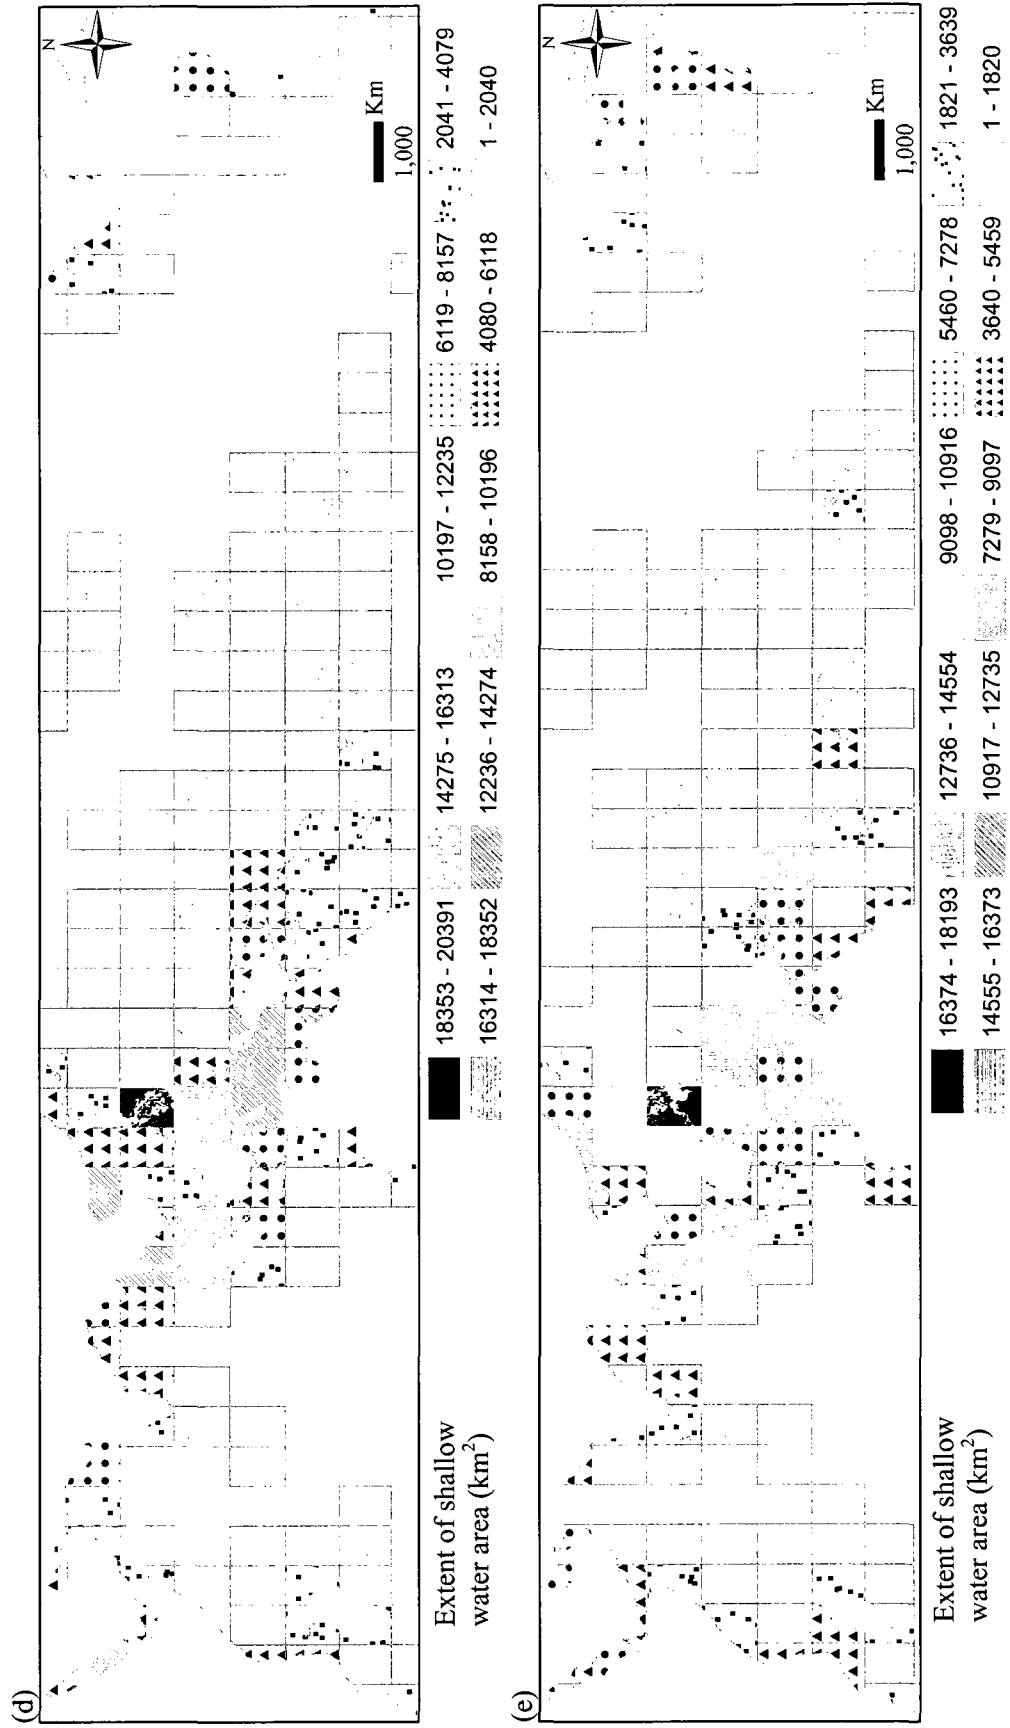

Fig. 9 *continued*

Greatest shallow water area and longest coastline per unit area (yellow to red) are mostly concentrated in the Coral Triangle; however, these two habitat predictors are not evenly distributed within the Coral Triangle (Figs. 8 & 9). As expected, the greatest concentration of shallow water area is over the Sunda and Arafura shelves, which are the two largest tropical shelf areas in the world (see Fig. 1). When using finer scale grids, however, high shallow water areas are also found in Mozambique, the Seychelles, the Red Sea, the Persian Gulf, coasts of Pakistan and India, Bangladesh, China, the Philippines, Panama, and Peru (Fig. 8a). Similar high shallow water locations are recorded using medium grids (Fig. 8b), except for Mozambique, the Seychelles, Pakistan, India, Bangladesh, Panama, and Peru. For large and UTM (Figs. 8c-g) grids, the largest available shallow water habitat areas are detected only for the Sunda and Arafura shelves.

The cells with the longest coastline most often do not coincide with the large shallow water areas of the Sunda and Arafura shelves (Figs. 8 & 9). The location of high coastline concentration generally is found in the Philippines and eastern Indonesia. However, this differs according to the grid resolution, with smallest cell sizes picking up localized high coastline concentrations, and lower resolution large cells picking up more regional coastline concentrations. The longest coastlines are located along the Gulf of Tonkin in the boundary of Vietnam and China, the Mergui Archipelago in southwestern Myanmar, the coast around Waigeo and Salawati of the Bird's Head region of northwest Papua (Indonesia), and the Buccaneer Archipelago region of Western Australia at smallest grid sizes (Fig. 9a). For the medium grid (Fig. 9b), coastline concentrations remain in the Mergui Archipelago region of Myanmar, and also extend to the Buccaneer Archipelago, in the Gulf of Tonkin, and in the region around the tip of Peninsular Malaysia. For the large grid (Fig. 9c), greatest coastline concentrations are found around northern Taiwan and Fujian and Zhejiang coastlines of China, Western Australia, and the Bird's Head region. The UTM grid (Fig. 9d) records the highest coastal concentration in the central Philippines. Shifting the UTM grid north-south and northeast retains the highest coastline concentration in the Philippines, while shifting it east-west relocates this to the Bird's Head region (Figs. 9e-g).

The amount of variation in species richness explained in regression analyses differs according to available habitat predictors and grid size resolution (Table 2; Fig. 10). Regression analyses of species richness versus shallow water area and coastline length are significant ($p < 0.001$) at all grid sizes, although most of the R^2 values were low. The amount of variation explained in species richness also increases with decreasing grid resolution (increasing cell size), with the highest variation explained in the UTM grid. Changing the locations of the UTM grid

by half a cell size north/south, east/west, and northeast/southwest alter the amount of variation explained by the shallow water area in the analyses, but these changes are generally small. However, the difference in the amount of variation explained by coastline length varies more in shifting UTM positions.

Table 2 Results of the analysis of the species richness (S) against shallow water area (SW) and coastline length (CL) in the Indo-Pacific region using Poisson regression models. R^2 value shows the amount of variation explained, while P value indicates the significance of the relationship.

Grid size/ position	S vs. SW		S vs. CL	
	R^2	P value	R^2	P value
Small	0.076	<0.001	0.077	<0.001
Medium	0.148	<0.001	0.165	<0.001
Large	0.216	<0.001	0.182	<0.001
UTM	0.260	<0.001	0.329	<0.001
UTM _{north/south}	0.248	<0.001	0.172	<0.001
UTM _{east/west}	0.252	<0.001	0.226	<0.001
UTM _{northeast/southwest}	0.268	<0.001	0.236	<0.001

The amount of variation in species richness explained by both of the habitat heterogeneity indices in regression analysis is generally very low using grids (Table 3; Fig. 10). However, the habitat diversity index regressions were significant at all grid sizes ($p < 0.01$) while only the medium grid showing a significant result ($p < 0.05$) for patch density. The habitat diversity index in larger grid sizes appeared to explain slightly more variation in species richness than smaller grid sizes. Habitat heterogeneity indices generally explain less of the variation in species richness than the available habitat predictors (Fig. 10).

Table 3 Results of the analysis of the species richness (S) against habitat diversity index (HDI) and patch density (PD) in the Indo-Pacific region using Poisson regression models. R^2 value shows the amount of variation explained, while P value indicates the significance of the relationship.

Grid size/ position	S vs. HDI		S vs. PD	
	R^2	P value	R^2	P value
Small	0.031	<0.001	0.002	0.125
Medium	0.040	<0.001	0.009	0.027
Large	0.072	<0.001	0.004	0.372

UTM _{east/west}	0.062	<0.001	0.007	0.265
UTM _{northeast/southwest}	0.080	<0.001	0.012	0.162

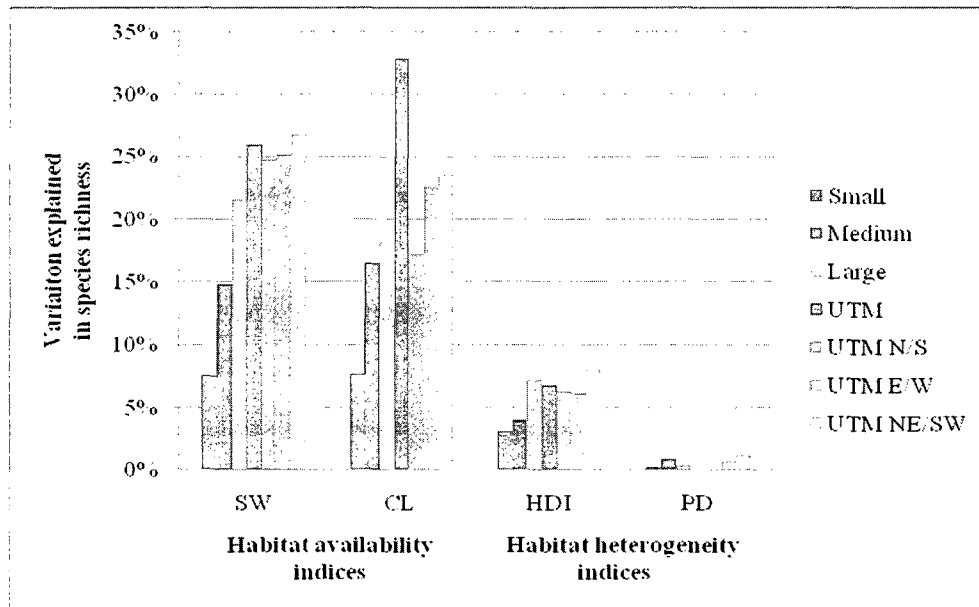

Figure 10 Analysis of factors influencing biodiversity of species in the Indo-Pacific region, illustrated by the percent variation as explained by shallow water habitat area (SW), coastline length (CL), habitat diversity index (HDI), and patch density (PD) for different grid sizes (small, medium, large, and UTM) and different UTM positions (north/south, east/west, and northeast/southwest). Habitat availability indices explained the more variation than the habitat heterogeneity indices.

The amount of variation in species richness explained by the available habitat predictors is generally greater in the ETP than the IWP (Table 4; Figs. 11 & 12). In the IWP, regression analysis is significant ($p < 0.001$) in all grids for both shallow water area and coastline length, with higher R^2 value for coastline than the shallow water area. A decrease in grid resolution results in an increase in the amount of variation explained by both shallow water area and coastline length. An abrupt change in the R^2 value for coastline length is noted when the UTM is shifted to north/south and east/west. In the ETP, the variance explained by the shallow water area and coastline length are significant ($p < 0.05$) in all grid sizes, with the exception of coastline length in large grid sizes. Increasing grid resolution and shifting the UTM positions show no evident trend in the R^2 values for shallow water area. For coastlines in the ETP region, small, medium, and large grids have lower R^2 values compared to that of the UTM grids. In most cases, the extent of shallow water area explains the species richness more than the length of the coast in the ETP but in some cases the differences are slight.

The amount of variation explained by the habitat heterogeneity indices was generally very low but generally greater in the IWP than the ETP (Table 5; Figs. 11 & 12). In the IWP, the amount of variation in species richness explained by habitat diversity index and patch density is significant ($p < 0.05$) only in small, medium, and large grids. In ETP, both habitat diversity index and patch density do not show a significant relationship in explaining the amount of species among all grid sizes and varying UTM positions.

Table 4 Results of the analysis of the species richness (S) against shallow water area (SW) and coastline length (CL) in the IWP and ETP using Poisson regression models. R^2 value shows the amount of variation explained, while P value indicates the significance of the relationship.

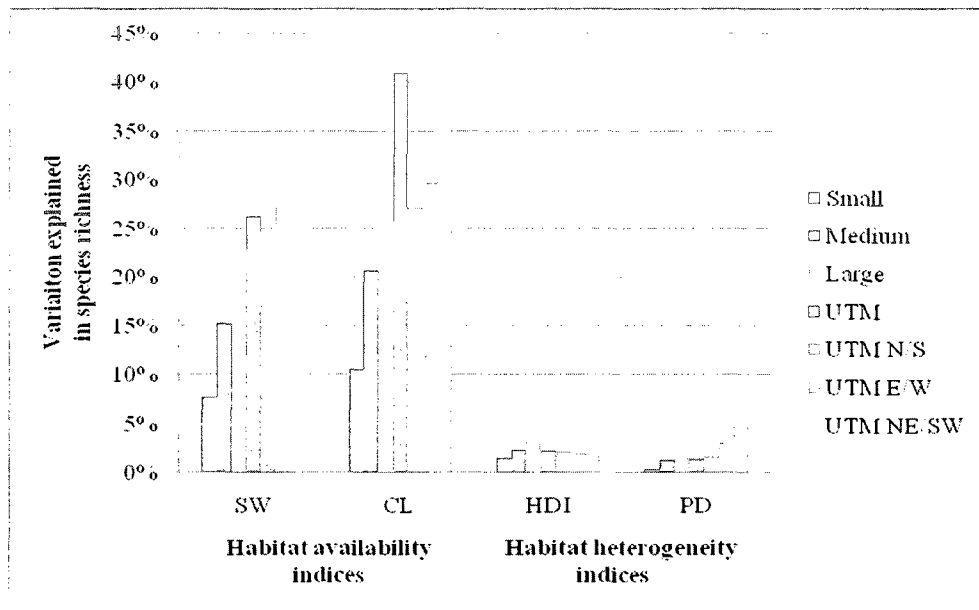

Figure 11 Analysis of factors influencing biodiversity of species in the IWP, illustrated by the percent variation as explained by shallow water habitat area (SW), coastline length (CL), habitat diversity index (HDI), and patch density (PD) for different grid sizes (small, medium, large and, UTM) and different UTM positions (north/south, east/west, and northeast/southwest). Habitat availability indices explained the more variation than the habitat heterogeneity indices.

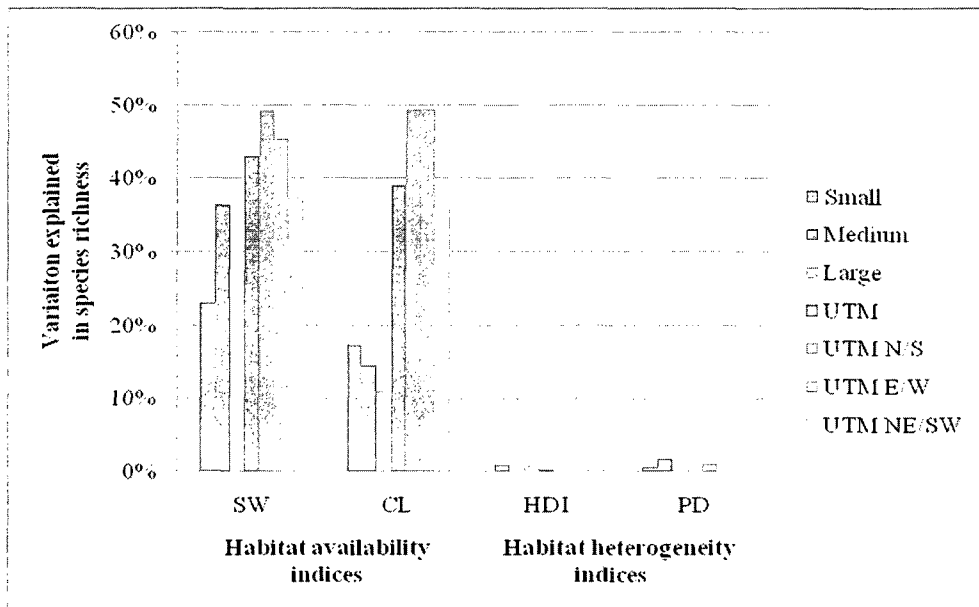

Figure 12 Analysis of factors influencing biodiversity of species in the ETP, illustrated by the percent variation as explained by shallow water habitat area (SW), coastline length (CL), habitat diversity index (HDI), and patch density (PD) for different grid sizes (small, medium, large and, UTM) and different UTM positions (north/south, east/west, and northeast/southwest). Habitat availability indices explained the more variation than the habitat heterogeneity indices.

The results of regression analyses for species richness versus habitat availability predictors vary when grids are classified as either coastal, continental, or oceanic with largest R^2 values in the continental classification (Table 6; Figs. 13-15). In the coastal zone, shallow water area and coastline length are significant ($p < 0.10$) in explaining the amount of variation in species richness only at large and UTM grid sizes. Increasing grid sizes and varying UTM positions in coastal zones do not show any trend in explaining the amount of variation in species richness. Grids located on continental shelves show a trend of increasing R^2 values in increasing grid size for shallow water area although the relationship is only significant ($p < 0.05$) at medium grid size and in specific UTM positions. Shifting the UTM grid half a cell east/west and northeast/southwest result in a dramatic change in the amount of variation explained in species richness by shallow water area, with a significant relationship ($P < 0.01$). The amount of variation explained by the coastline length in species richness in continental zones show significant results ($p < 0.05$) for some grid sizes. Although continental grids do not contain continental coast, they do include offshore islands found within the 200m bathymetry. In contrast to oceanic islands found in the open ocean, both shallow water area and coastline length significantly ($p < 0.01$) affect species richness. Increasing grid sizes in these islands show increasing R^2 values, with the coastline length explaining more variation. There is no evident trend, however, in the amount of variation explained by shallow water area and coastline length when shifting the position of the UTM grid.

The amount of variation in species richness explained by habitat heterogeneity indices in coastal, continental, an oceanic zones is generally greater compared to that explained by the habitat availability predictors (Table 7; Figs. 13-15). Along the coasts, the amount of variation show almost identical values for habitat diversity index and patch density, with all R^2 values significant ($P < 0.01$). Increasing grid resolution and changing UTM positions do not change regression results appreciably. The habitat diversity index explains more variation than patch density at continental shelves and oceanic islands. Increasing grid resolutions and shifting UTM grids also do not change regression results appreciably in these zones.

Table 6 Results of the analysis of the species richness (S) against shallow water area (SW) and coastline length (CL) in coastal, continental, and oceanic zones using Poisson regression. R^2 value shows the variance explained, while P value indicates the significance of the relationship.

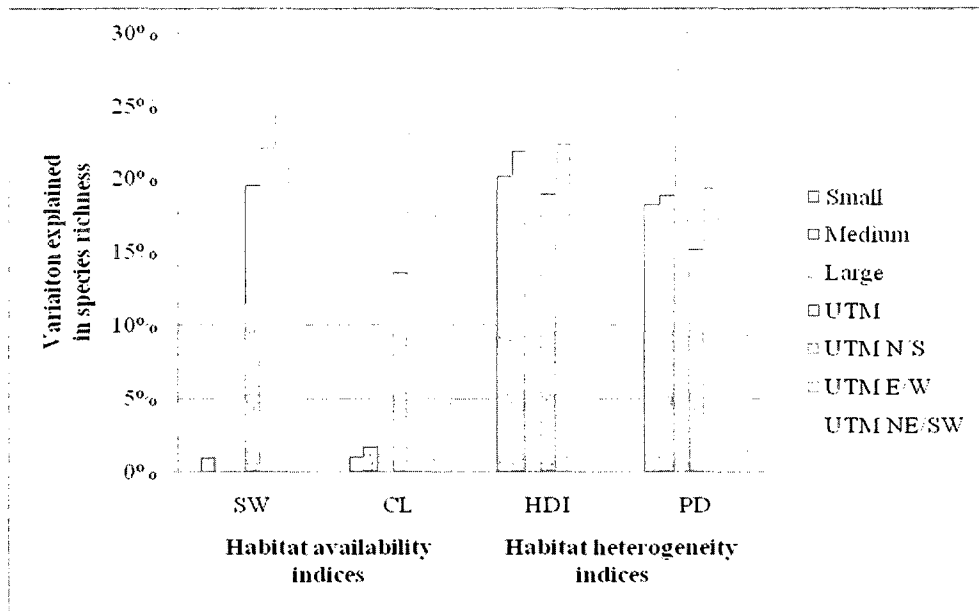

Figure 13 Analysis of factors influencing biodiversity of species in coastal zones, illustrated by the percent variation as explained by shallow water habitat area (SW), coastline length (CL), habitat diversity index (HDI), and patch density (PD) for different grid sizes (small, medium, large, and UTM) and different UTM positions (north/south, east/west, and northeast/southwest). Habitat heterogeneity indices explained the more variation than the habitat heterogeneity indices.

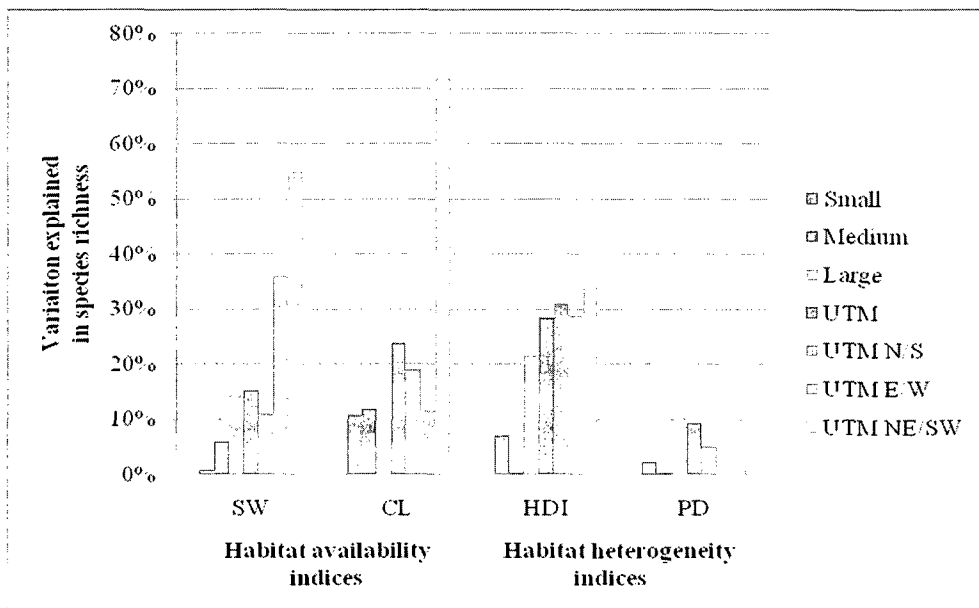

Figure 14 Analysis of factors influencing biodiversity of species in continental zones, illustrated by the percent variation as explained by shallow water habitat area (SW), coastline length (CL), habitat diversity index (HDI), and patch density (PD) for different grid sizes (small, medium, large, and UTM) and different UTM positions (north/south, east/west, and northeast/southwest). Habitat availability indices explained the more variation than the habitat heterogeneity indices.

Figure 15 Analysis of factors influencing biodiversity of species in oceanic zones, illustrated by the percent variation as explained by shallow water habitat area (SW), coastline length (CL), habitat diversity index (HDI), and patch density (PD) for different grid sizes (small, medium, large and UTM) and different UTM positions (north/south, east/west, and northeast/southwest). Habitat availability indices explained the more variation than the habitat heterogeneity indices.

Species curves for shallow water area versus the habitat availability and the habitat heterogeneity indices show a logarithmic trend, with changing slopes and pattern at different grids (Figs. 16-29). Slopes are generally low at all grid types, but appear to be steeper at large and UTM grids, primarily due to fewer distribution points. Positive slopes are seen in most of the shallow water area curves at all types of grids. All curves for coastline length have positive slopes. Curves for both of the habitat availability predictors show a pattern of clumping near the zero mark, which indicates the high frequency of grids registering a low habitat concentration. On the other hand, species curves for habitat diversity index show that some points are distributed away from the trend line and not as tight as the point distributions in shallow water area and coastline length curves. The majority of these curves have either negative or flat slopes, especially at grids assigned in ETP. Patch density curves are mostly flat and have negative slopes. The appearance of the species curves generally indicates that habitat availability indicators are better predictors of species richness compared to the habitat heterogeneity indices.

(a-d) Coastal; (e-h) Continental; (i-l) Oceanic.

Low R^2 values and species curves with negative slopes for habitat diversity index and patch density is potentially a result of the uneven distribution of shallow water area when using grids. To isolate the effect of area shallow water habitat (200m bathymetry) was divided into equal area sections (1000, 500, and 100), with one of the equal area sections partitioned in a different orientation (100b). Regression analysis reveals a significant effect ($p < 0.001$) for both habitat species diversity and patch density in explaining the amount of variation in species richness (Table 8; Fig. 30). R^2 values are still low, but higher than the R^2 values from grid analyses. Increasing cell sizes show increases the amount of variation explained, but a shift in partition orientation appears to have a small effect. Nevertheless, this approach of partitioning by equal area sections shows it to be more effective in explaining the amount of variation caused by the habitat heterogeneity indices. In addition, the species area curves for both the habitat diversity index and patch density, at different equal area sections, show a tight point distributions with increasing slopes (Fig. 31). Contrary to the result in grid analysis, habitat heterogeneity appears to play a role in shaping biodiversity patterns in the Indo-Pacific.

Table 8 Results of the analysis of the species richness (S) against habitat diversity index (HDI) and patch density (PD) using equal area sections (EAS) in Poisson regression models. R^2 value shows the amount of variation, while P value indicates the significance of the relationship.

The measures of habitat availability and habitat heterogeneity indices differ across the 24 LMEs in the Indo-Pacific region (Table 9). The top three LMEs with the highest species richness (Sulu-Celebes Sea, Indonesian Sea, and Papua-Solomons) are all found in the Coral Triangle. The LMEs with the largest shallow water area are found in South China Sea, Indonesian Sea, and

North Australian Shelf, all of which are within the Sunda and Arafura shelves. The longest coastline length is found in the Indonesian Sea, followed by the South China Sea, and the Bay of Bengal. These LMEs are also located within the boundaries of the Coral Triangle. The LMEs having the highest value of habitat diversity index are spread out in the entire Indo-Pacific – the Red Sea, Pacific Ocean Islands, and Sulu-Celebes Sea. Patch density is highest in the Kuroshio Current, Pacific Ocean Islands, and Northeast Australian Shelf.

Table 9 Species richness and habitat measures of the 24 Large Marine Ecosystems (LMEs) in the Indo-Pacific. LMEs are arranged by decreasing mean number of species per grid size (Mean Sp). The total shallow water area (SW), total coastline length (CL), habitat diversity index (HDI), and patch density (PD) per LME are given. PD for ECA is considered as outlier (*) and not included in statistical analysis (see Fig. 35).

Regression analyses of species richness versus habitat availability and habitat heterogeneity indices vary widely using the modified LMEs (Figs. 32-35). Only the habitat heterogeneity index has a significant effect ($p < 0.01$) in explaining the amount of variation in species richness per LME (Fig. 34). The habitat diversity index explained about 31% of species richness. In the species curves, all points of the LMEs located within the boundaries of the Coral Triangle (South China Sea, Sulu-Celebes Sea, Indonesian Sea, and Papua-Solomons) are consistently found at the top of the logarithmic trendline. Most of the points at the bottom of the trendline belong to LMEs found within the Indian Ocean and ETP.

DISCUSSION

Overlay analysis using 7,859 distribution maps of fishes, invertebrates (molluscs and crustaceans), and habitat-forming species (corals, seagrasses, and mangroves) gives further support to the findings of Carpenter & Springer (2005) that the Philippines is the global epicenter of marine biodiversity. This study also supports the secondary diversity found in Indonesia and the general pattern of decreasing species richness with distance from the epicenter (Hoeksema, 2007). Carpenter & Springer's (2005) results showed a peak in diversity in the Verde Island Passage, which is between the islands of Mindoro and Luzon, while this study shows the peak in the waters surrounding the islands of Panay, Negros, Cebu, and Bohol (Fig. 6). This slight southward shift is potentially attributed to different GIS methodology such as the different basemaps used in the two studies. However, most likely the difference is because of the different biotic composition of the different studies. Carpenter and Springer (2005) used distributions of a broad range of taxa of commercial importance including seaweeds, a wide range of invertebrates, fishes from many different habitats, and higher vertebrates such as turtles and marine mammals. The present study is biased toward coral reef fishes and a plot of only coral reef fishes (Fig. 7b) shows a peak of diversity very similar to the peak revealed in the overall analysis (Fig. 6). This study utilized distributions of 7,859 species, of which 4,043 were coral reef fishes while Carpenter and Springer (2005) used distributions of 2,983 species of potential commercial importance. While these studies agree very closely with the general biodiversity pattern of the Coral Triangle, both are in marked contrast to the pattern revealed by Bellwood *et al.* (2005). They show an observed species richness pattern for fishes as greatest around the northeastern and southeastern island of Papua. This is likely because of the haphazard choice of fish families based on available published distribution maps (only 1,766 species belonging to 13 families versus 5,616 shore fishes belonging to 188 families, in this study). The observed pattern of richness for corals in Bellwood *et al.* (2005) is similar to this study because both were based on a similar set of published maps (Veron, 2000).

The area of refuge hypothesis suggests that the high diversity of species in the Coral Triangle is mainly influenced by the available shallow water habitat. However, this study shows that shallow water area, as a measure of available habitat, has only a small influence in shaping the species richness in the region, both spatially and statistically. Spatial analysis shows that the location of the largest shallow water area, found in the Sunda and Arafura shelves, does not coincide with the location of highest shore species biodiversity, which is found in the Philippines.

Moreover, shallow water area only accounts for a maximum of 27% of variation in species richness (Table 2), which is lower compared to what is noted in previous studies. Bellwood & Hughes (2001) showed that the amount of variation explained by shallow water habitat is about 42% and 57% in corals and fishes, respectively. This disparity can be attributed to the different methods employed, including the use of point data for species distribution and the extent of shallow water area used (50m compared to 200m, in this study). Nevertheless, both spatial and statistical tests reveal that shallow water area, as a function of habitat, is not a strong predictor of species richness as previously thought.

This study also tests how shoreline concentration, as a proxy of available habitat, explains the biodiversity in the Indo-Pacific region. Spatial and statistical analyses both show that coastline length is a better proxy of available habitat area compared to available shallow water area. Spatial analysis shows that the longest coastline is most consistently found in the Philippines and eastern Indonesia at grid sizes with the highest R^2 values (Figs. 9d,f, & g) – the same locations where the highest 10% of species richness is found (Fig.6). The amount of variation in species richness explained by coastline concentration is about 33%, which is higher than that explained by shallow water area, with only 27% (Table 2; Fig. 10). These findings are consistent with the results of Etnoyer (2001), who showed that coastline length was a good proxy for area based on the “shoreline complexity” hypothesis. The hypothesis suggests that an intricate and convoluted shoreline in a grid could increase the amount of available habitat by two or three fold, compared to a simpler shoreline in the same grid. Coastline complexity, therefore, is the best predictor of species richness in this study. The Coral Triangle has the most concentrated coastline in the Indo-Pacific region, contributed by the numerous islands in the archipelagos of the Philippines and Indonesia. Although the availability of shallow water habitat is important, a more complex shoreline is also important for many fishes and invertebrates during their early life history stages (Peterson *et al.*, 2000).

The very weak influence of habitat heterogeneity in explaining the amount of variation in the Indo-Pacific (Table 3; Fig. 10) appears to agree with the habitat *per se* hypothesis (Kallimanis *et al.*, 2008), and falsifies the notion that habitat heterogeneity supersedes the effect of available habitat (Tews *et al.*, 2004; Báldi, 2008). This result, however, can be attributed to the poor correlation of both habitat diversity index and patch density to species richness, which are mainly due to the limitations when using grids. The use of Shannon-Weiner formula in calculating the habitat heterogeneity index is different from other methods that used discrete counts of habitat types (Magurran, 1988; Tews *et al.*, 2004). This study uses the area measurements (continuous

variables) of coral reefs, seagrass beds, mangals, and soft-bottom as substitutes for count variables. Since area measurement is used instead of counting the elements, the habitat diversity index calculation was highly variable depending on the area of the dominant soft-bottom habitat. The WCMC layers (coral reefs, seagrass beds, and mangals) are very tiny, compared to the soft-bottom layer derived from the shallow water area shapefile. In grids where the area of soft-bottom is larger than the area of all other habitat types, habitat diversity index will be low. In comparison with another grid where the area of soft-bottom is smaller than the area of all other habitat types within the same grid, habitat diversity index will be high. The uneven soft-bottom area thus creates highly variable habitat diversity indices that may not reflect accurately the species richness of the grid.

Similarly, the calculation of patch density is also influenced by the shallow water area habitat (Table 3; Fig. 10). Since patch density measures the number of patches (polygons) of coral reefs, seagrass beds, mangals, and soft-bottom over shallow water area, high patch density is expected in grids with lower shallow water area. Conversely, grids with low patch density are likely to contain larger amounts of shallow water area. Given that species richness is positively correlated to the amount of available shallow water area, a negative correlation between patch density and species richness is expected when using grids. This can also be seen in the species-area curves, where most of the curves for patch density show a flat or decreasing trend.

Problems with the variability in shallow water area per grid in calculating the habitat heterogeneity indices are addressed by keeping the shallow water area constant in equal area sections (Fig. 4). When shallow water area is kept constant, habitat heterogeneity indices reveal a significant effect on the amount of variation in species richness (Table 8; Fig. 30). The result is similar to the findings of Kallimanis *et al.* (2008), who note that habitat heterogeneity supersedes the available habitat if area is kept constant. Species-area curves for the habitat diversity index and patch density both show a positive trend (Fig. 31). The results suggest that habitat heterogeneity also influences the species richness in the Indo-Pacific region, given equal areas of available habitat. Habitat diversity index and patch density, however, explains only about 13% and 15% of species richness, respectively (Table 8). The low variation explained in species richness by habitat heterogeneity disagrees with the results that heterogeneity is the most important factor shaping species-area relationships (Rosenzweig, 1995; Tews *et al.*, 2004; Báldi, 2008). However, habitat availability and habitat heterogeneity both play an important, but not overwhelming role, in shaping the species richness in the Indo-Pacific as indicated by significant R^2 values (Tables 2 & 8).

Larger grids generally explain a greater amount of variation in species richness by the habitat availability predictors than smaller grids (Tables 2 & 3), probably because smaller grids are not reflective of the spatial scales that the generalized species distributions of the species in this study. Distributions of marine species in the Indo-Pacific are overwhelmingly wide ranging, especially coral reef species (Allen, 2007). Using smaller grids, the top 40% of shallow water habitat area is shared by Southeast Asia, Australia, Papua (including the Sunda and Arafura shelves) and by some locations in Africa and the ETP (Figs. 8a & b). The size of each unit cell is small and, therefore, numerous potential areas with high shallow water habitat will be identified, including areas with low species richness (compare Figs. 8a & b with Fig. 6a). The same effect is observed when looking at the coastline length using smaller grids. Several areas with the top 40% of coastline are found in places not expected to be as diverse (compare Figs. 9a & b with Fig. 6a). Therefore, using a higher resolution cell size (i.e. smaller grid) does not necessarily produce a better fit of the habitat variable with species richness. This is reflective of the large average distribution area of species in this study that would not be detected at small grid sizes. This is also reflected in the regression values for species richness with shallow water habitat area and coastline length that increase from small, medium, large, and UTM grids, respectively. Therefore, grid resolution size can influence habitat predictors of species richness and the UTM grid achieves the best fit in this study. However, using grid sizes larger than UTM warrants further testing. This would increase the amount of available habitat per grid and may result in an increase in R^2 value.

Changing centroid position of grids can markedly influence results since shifting position will variably change the shallow water area and coastline length covered, and may result to abrupt changes in the R^2 values (Tables 2 & 3; Fig. 10). The random differences in land and sea areas covered when centroids are shifted will also influence which cells are reclassified to reduce the effect of differences in land included in the grids. This adds to effective grid size variability and may also affect R^2 values in regression analyses. Increasing size of equal area sections also increased the amount of variation explained in species richness (Table 8; Fig. 30). A larger grid tends to capture larger habitat area and more diverse habitats, thus a higher number of species. Although size affects the amount of variation, centroid location, however, did not appreciably change results. Unlike in grids, there is no need to combine the equal area sections when centroids are shifted. Thus, the variability in effective grid size is eliminated in using the equal area sections.

The amount of variation in species richness as explained by habitat availability predictors and habitat heterogeneity indices changes appreciably when grids are subdivided into coastal, continental, and oceanic zones (Tables 6 & 7; Figs. 13-15). This subdivision was also meant to reduce the effects of unequal land sizes using grids. In coastal zones, all the factors tested in this study have a strong influence on species richness, except for some small and medium grid sizes. Shallow water area and the coastline concentration are expected to affect species diversity since both only consider parameters at or near the coast. Also, the high correlation of species richness and habitat heterogeneity indices can be attributed to the fact that the majority of habitat-forming species are concentrated near the coast. In oceanic zones, species richness is shown to be affected by only shallow water area, coastline length, and habitat diversity index. Coastline length explains the most variation in species richness in islands because they have a low amount of shallow water area, and the habitat-forming species are very few. In continental zones, species richness is mostly influenced by the shallow water area and coastline length. The reason why habitat availability is more important than heterogeneity in continental zones is due to the high concentration of soft-bottom habitats in this zone. Soft-bottom habitats are more widespread here than coral reefs, seagrass beds, and mangals.

The effects of habitat availability and habitat heterogeneity have marked contrasts in the IWP and ETP regions because of the fundamental differences in oceanic influences and habitat types (Randall, 1998). In addition, the vast expanse of ocean between Polynesia and Easter Island, which serves as a barrier between the two regions (Ekman, 1953), limits dispersal and subsequent mixing of biota between the regions. Species richness in the IWP is influenced by both habitat availability and habitat heterogeneity, while species richness in the ETP is greatly influenced by available habitats (Tables 4 & 5; Figs. 11 & 12). The rich geological history of the IWP (Renema *et al.*, 2008), the extent of available shallow water area (Carpenter, 1998), the greatest coastline concentration (Etnoyer, 2001), and the numerous habitat-forming species (Rosen, 1971, 1988a; Veron, 1995; Palumbi, 1997), all contribute to the amount of biodiversity in the region. On the other hand, the lack of habitat-forming species in the ETP possibly resulted in a biodiversity that greatly depends on the amount of shallow water area and coastline length, and not in the habitat heterogeneity in the region. Due to the upwelling process, coral reefs in the ETP are poorly developed and subject to rapid bioerosion (Manzello *et al.*, 2008). The coastlines in ETP are simpler than those found in IWP hence the effect of coastline does not differ much from the effects of shallow water area in ETP.

In LMEs (Fig. 5), the species richness is only influenced by the habitat diversity index (Figs. 32-35). This could be explained by the way LMEs are characterized using physical and ecological characteristics, e.g. bathymetry, hydrography, productivity, and trophic relations (Sherman & Hempel, 2009), so it is expected that species richness in LMEs is controlled by habitat availability. However, the effects of habitat heterogeneity may be stronger at larger scales. Larger habitat areas are more likely to have a wider array of habitats, which leads to a higher number of species. All LMEs in the boundaries of the Coral Triangle have the highest concentration of shallow water area, coastline length, habitat diversity index, and patch density than the other LMEs located outside of the Coral Triangle. This further supports that the highest habitat availability and heterogeneity in the Coral Triangle influences high biodiversity.

In this study, the high concentration of species richness in the Coral Triangle can be attributed to the positive correlation between the species distribution and the availability of habitat area and heterogeneity of habitat in the region. However, the low amount of variation contributed by area in this study is surprising given the high importance of available area in other studies (Rosenzweig, 1995; Bellwood and Hughes, 2001), as well as the effect of habitat heterogeneity (Báldi, 2008; Tews *et al.*, 2004). Given the amount of variation explained by both area and habitat heterogeneity, biodiversity in the Coral Triangle may possibly have been driven by other factors that are not tested in this study. The results of this thesis merit further study with focus on other factors that might have also contributed to the generation of diversity in a local scale, such as within the Coral Triangle. This can include identification of population structure within the Coral Triangle using molecular techniques and understanding the past and present marine biogeography patterns that have helped shape the diversity in the region. The GIS data used in this study can also be used to test the other hypothesis explaining the diversity in the Coral Triangle, particularly the center of overlap theory. Distribution maps can be analyzed to look for the amount of species occurring in Indian Ocean and West Pacific that overlap within the Coral Triangle.

The species richness pattern LME point location in species-area curves reveals potential priority areas for conservation management. This study reveals that the highest marine biodiversity is in the central Philippines, thus, suggesting that this area needs to be prioritized for conservation and management.

CONCLUSION

This study tested the effects of the area of refuge hypothesis in Indo-Pacific marine biogeography. Different manipulations of distribution maps using GIS reveal that species richness is found to be explained by both available habitat and habitat heterogeneity. Both availability of shallow water area and coastline length, as a proxy for available habitat, significantly impact species richness in the Indo-Pacific region. However, coastline length per unit area is a better predictor of species richness than availability of shallow water area. Habitat heterogeneity also influences biodiversity in the Indo-Pacific, however, this effect is weak compared to available habitat. The Coral Triangle generally has the most complex coastlines, extent of shallow water area and highly heterogeneous habitats – all contributing to its having the most diverse marine fauna in the world. Overall, the effects of both habitat availability and habitat heterogeneity are low; therefore other factors might have played a major role the biodiversity in the region. Possible reasons may include the availability of optimal climate, temperature, and primary production that allow organisms to subsist. Other possible factors that might influence the biodiversity in Coral Triangle that still warrant testing are that the Coral Triangle is the center of origin where lineages diversified, that species have accumulated there by ocean currents or complex geological shifts in shallow seas, and that it is the center of overlap between Indian and Pacific Ocean biotas.

Habitat availability and heterogeneity act at different intensities in explaining the species richness per region, zone, and LME. In the IWP, the species richness is influenced by both habitat availability and heterogeneity, but species richness in ETP is more likely to be influenced by available habitat. Coastal species are affected by shallow water area, coastline length, habitat diversity index, and patch density. Species richness in the islands is influenced by all factors except patch density. In continental zones, shallow water area and coastline length explain more variation in species richness than by the habitat diversity index.

Finally, this study has contributed to the expanding field of marine GIS by showing that GIS can also be employed to test and explain the pattern of species distributions in the marine environment. Previous studies that have employed GIS are mostly terrestrial (e.g. plants) or non-marine (e.g. insects, mammals) studies. The methods used in previous studies are modified to suit the requirements of the dataset in this study. Likewise, the methods and analyses employed and conducted in this study can be customized to identify areas of concern for priority management of other taxa at local, regional or global scale.

APPENDIX 1

LIST OF SPECIES DISTRIBUTION MAPS USED IN THIS THESIS

Kingdom	Phylum	Class	Order	Family	Species Name	Map References
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Acanthus ebracteatus</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Acanthus ilicifolius</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Acanthus volubilis</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Acanthus xiamenensis</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Filicopsida	Polypodiales	Pteridaceae	<i>Acrostichum aureum</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Filicopsida	Polypodiales	Pteridaceae	<i>Acrostichum danaeifolium</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Filicopsida	Polypodiales	Pteridaceae	<i>Acrostichum speciosum</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Caryophyllales	Plumbaginaceae	<i>Aegialiis annulata</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Caryophyllales	Plumbaginaceae	<i>Aegialiis rotundifolia</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Ericales	Myrsinaceae	<i>Aegiceras corniculatum</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Ericales	Myrsinaceae	<i>Aegiceras floridum</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Sapindales	Meliaceae	<i>Aglaiia cucullata</i>	Spalding <i>et al.</i> , 1997
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Amphibolis antarctica</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Amphibolis griffithii</i>	Green & Short, 2003
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia alba</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia bicolor</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia germinans</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia integra</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia marina</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia officinalis</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Acanthaceae	<i>Avicennia rumphiana</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Brownlowia argentea</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Brownlowia tersa</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Bruguiera cylindrica</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Bruguiera exaristata</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Bruguiera gymnorhiza</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Bruguiera hainesii</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Bruguiera parviflora</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Bruguiera sexangula</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Camptostemon philippinense</i>	Spalding <i>et al.</i> , 1997

Appendix 1 continued

Kingdom	Phylum	Class	Order	Family	Species Name	Map References
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Campostemon schultzei</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Ceritops australis</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Ceritops decandra</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Ceritops tagal</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Ceritops zippeliana</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Myrtales	Combretaceae	<i>Conocarpus erectus</i>	Spalding <i>et al.</i> , 1997
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Cymodocea angustata</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Cymodocea rotundata</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Cymodocea serrulata</i>	Green & Short, 2003
Plantae	Magnoliophyta	Magnoliopsida	Fabales	Fabaceae	<i>Cynometra iripa</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Ericales	Ebenaceae	<i>Diospyros littorea</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Lamiales	Bignoniaceae	<i>Dolichandrone spathacea</i>	Spalding <i>et al.</i> , 1997
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Enhalus acoroides</i>	Green & Short, 2003
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Euphorbiaceae	<i>Excoecaria agallocha</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Euphorbiaceae	<i>Excoecaria indica</i>	Spalding <i>et al.</i> , 1997
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Halodule beaudetiei</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Halodule pinifolia</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Halodule uninervis</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Cymodoceaceae	<i>Halodule wrightii</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila australis</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila beccarii</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila capricorni</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila decipiens</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila euphlebia</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila gaudichaudii</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila hawaiiensis</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila major</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila mikii</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila okinawensis</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila ovalis</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila ovata</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila spinulosa</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila stipulacea</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila sulevisii</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Hydrocharitaceae	<i>Halophila tricornata</i>	Green & Short, 2003
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Heritiera fomes</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Heritiera globosa</i>	Spalding <i>et al.</i> , 1997

Kingdom	Phylum	Class	Order	Family	Species Name	Map References
Plantae	Magnoliophyta	Magnoliopsida	Malvales	Malvaceae	<i>Heritiera littoralis</i>	Spalding <i>et al.</i> , 1997
Plantae	Tracheophyta	Liliopsida	Alismatales	Zosteraceae	<i>Heterozostera chilensis</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Zosteraceae	<i>Heterozostera polychlamys</i>	Green & Short, 2003
Plantae	Tracheophyta	Liliopsida	Alismatales	Zosteraceae	<i>Heterozostera tasmanica</i>	Green & Short, 2003
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Kandelia candel</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Malpighiales	Rhizophoraceae	<i>Kandelia obovata</i>	Spalding <i>et al.</i> , 1997
Plantae	Magnoliophyta	Magnoliopsida	Myrtales	Combretaceae	<i>Laguncularia racemosa</i>	Spalding <i>et al.</i> , 1997

Jonnell C. Sanciangco

Department of Biological Sciences, Old Dominion University
Norfolk, Virginia 23529

Jonnell Cueto Sanciangco was born in Batangas, Philippines on March 28, 1981, to Jessie M. Sanciangco and Juanita C. Sanciangco. He graduated as a Valedictorian from Padre Valerio Malabanan Memorial School in 1993 and graduated with honors from Lipa City National Science High School in 1997. Jonnell earned the Bachelor of Science in Biology, with major in Marine Zoology, at the University of the Philippines at Los Baños in April 2001, where he also worked as an Undergraduate Research Assistant during his last semester. Working with Dr. Kent Carpenter (Old Dominion University) from 2006 to 2007, Jonnell was privileged to work as a consultant for the International Union for the Conservation of Nature (IUCN) to create habitat distribution maps for the Eastern Tropical Pacific, and concurrently, with the Food and Agriculture Organization of the United Nations (FAO), also as a consultant, and contributed to the FAO Regional Guides for the Eastern Central Atlantic shorefishes. He entered the Masters in Biology program in the Department of Biological Sciences at Old Dominion University in August 2007. During his tenure as a Masters student, he earned his certificate in Geographic Information Science (GIScience) in Spring 2009. Jonnell currently works as a Graduate Research Assistant working for Dr. Kent Carpenter under the Global Marine Species Assessment Programme of the IUCN.

Presentations:

Sanciangco, J.C. & Carpenter, K.E. 2009. Habitat availability and species-area relationships of indo-pacific shore biota. Virginia Academy of Sciences (VAS) Annual Meeting, Virginia Commonwealth University, Richmond, VA.
