(Rceived 19 December 2014; published 26 February 2015)

We construct a coordinate-space chiral potential, including \( \Delta \)-isobar intermediate states in its two-pion-exchange component up to order \( Q^4 \) (\( Q \) denotes generically the low momentum scale). The contact interactions entering at next-to-leading and next-to-next-to-leading orders (\( Q^2 \) and \( Q^4 \), respectively) are rearranged by Fierz transformations to yield terms at most quadratic in the relative momentum operator of the two nucleons. The low-energy constants multiplying these contact interactions are fitted to the 2013 Granada database, consisting of 2309 \( pp \) and 2982 \( np \) data (including, respectively, 148 and 218 normalizations) in the laboratory-energy range 0–300 MeV. For the total 5291 \( pp \) and \( np \) data in this range, we obtain a \( \chi^2/datum \) of roughly 1.3 for a set of three models characterized by long- and short-range cutoffs, \( R_\ell \) and \( R_e \), respectively, ranging from \( (R_\ell, R_e) = (1.2, 0.8) \) fm down to \( (0.8, 0.6) \) fm. The long-range (short-range) cutoff regularizes the one- and two-pion exchange (contact) part of the potential.

I. INTRODUCTION

The nucleon-nucleon (NN) interaction is a basic building block in nuclear physics as it makes it possible to describe nuclear structure and nuclear reactions. If the forces were known accurately and precisely, the nuclear many-body problem would become a large-scale computation where precision and accuracy are defined in terms of the preferred numerical method. However, the lack of direct knowledge of the forces among constituents at separation distances relevant for nuclear structure and reactions drastically changes the rules of the game. Indeed, the use of a large but finite body of scattering data below a given maximal energy to provide constraints on the interaction transforms the whole setup into a statistical inference problem, based on the conventional least \( \chi^2 \) method. This fact was recognized already in 1957 [1] (see Ref. [2] for an early review) and, after many years, culminated in the admirable Nijmegen partial wave analysis (PWA) of 1993 [3], based on the crucial observations that charge-dependent one-pion-exchange (CD-OPE), tiny but essential electromagnetic and relativistic effects, and a judicious selection of the scattering database could actually provide a satisfactory fit with \( \chi^2/datum \sim 1 \) for a total number of data consisting, as of 1993, of 1787 \( pp \) and 2514 \( np \) (normalizations included) at the 3 \( \sigma \) level. These criteria have set the standard for PWA’s and the design of high quality phenomenological potentials [4–12]. The inference point of view is mainly phenomenological and requires a balanced interplay between which data qualify as constraints and which models provide the most likely description of the data. None of these choices is free of prejudices and they are actually intertwined—a circumstance that should be kept in mind when assessing the reliability and predictive power of the theory aiming at a faithful representation of the input data and their uncertainties.

The quantum mechanical nature of the PWA with a given cutoff in energy leads to inverse scattering ambiguities which increase at short distances (see, for example, Refs. [13,14] and references therein). Remarkably, a universal and model-independent low-energy interaction arises when unobserved high energy components above the cutoff are explicitly integrated out of the Hilbert space preserving the scattering amplitude [15,16]. While this \( \text{V}_{\text{low}-k} \) framework is an extremely appealing setup based on Wilsonian renormalization, to date this universal interaction has not been determined from data directly and one has to proceed via a fitted and bare NN interaction because off-shellness is required [17]. However, inferring an NN interaction from data, is not the full story, and three-nucleon, and possibly higher multinucleon, interactions are needed to describe residual contributions to nuclear binding energies [18]. As is well known, their strength and form are also affected by the chosen off-shell behavior of the NN interaction and a universal \( \text{V}_{\text{low}-k} \) three-nucleon interaction remains to be found.

In an ideal situation all steps in the inference process, including the scattering data selection itself, should be carried out with the “true” theory, which for nuclear physics is quantum chromodynamics (QCD), the fundamental theory of interacting quarks and gluons. Assuming, as we do, that the theory is correct, QCD would just tell us which experiments are right and which are wrong, or whether the reported uncertainties are realistic with a given confidence level on the side of the experiment. At the same time one would set constraints on the QCD parameters such as the light quark masses and \( \Lambda_{\text{QCD}} \), or equivalently the pion mass \( m_\pi \) and the pion weak decay constant \( F_\pi \). While there was impressive progress in bringing...
lattice QCD simulations for light quarks closer to nuclear physics working conditions (see Refs. [19,20] and references therein), we do not yet envisage, at least not in the near future, the realization of conditions that would allow one to establish, on QCD grounds, the correctness of the about 8000 currently available published $pp$ and $np$ scattering data below pion production threshold. Instead, already in the early 1990s the phenomenological analysis carried out by the Nijmegen group made it possible to pin down the pion masses with a precision of 1 MeV from their PWA of $pp$ and $np$ data [21].

In practice, we must content ourselves with an approximation scheme to the true theory in conjunction with a phenomenological approach. This specifically means assuming a sufficiently flexible parametrization of the interaction in terms of the relevant degrees of freedom which does not overlook some relevant physical feature. In what follows it is instructive to briefly review both the process and criteria taken into account to select a consistent database as well as the QCD-based theory used to describe it. Our aim is to make the reader aware of all the fine details which are needed to credibly falsify the theoretical model, QCD grounded or not, against the data and keep an open mind about the out-coming result.

On the theoretical side, we will assume along with Weinberg [22] that there is a chiral effective field theory ($\chi$EFT) capable of systematically describing the strong interactions among nucleons, $\Delta$ isobars, and pions, as well as the electroweak interactions of these hadrons with external (electroweak) fields. In the specific case of two nucleons, the requirements imposed by $\chi$EFT can be incorporated into a nonrelativistic quantum mechanical potential, constructed by a perturbative matching, order by order in the chiral expansion, between the on-shell scattering amplitude and the solution of the Schrödinger equation (see, for example, the review paper by Machleidt and Entem [23]). Such a theory provides the most general scheme accommodating all possible interactions compatible with the relevant symmetries of QCD at low energies, in particular chiral symmetry. By its own nature, $\chi$EFT needs to be organized within a given power counting scheme and the resulting chiral potentials can conveniently be separated into long- and short-distance contributions, the latter (short-distance ones) featuring the needed counterterms for renormalization. At leading order in the chiral expansion one has the venerable one-pion-exchange (OPE) potential which, as already mentioned, emerges as a universal and indispensable long-distance feature for an accurate description of proton-proton and neutron-proton scattering data [3]. Higher orders in the chiral expansion incorporate the two-pion-exchange (TPE) potential [24] from leading and subleading $\pi N$ couplings (the subleading couplings $c_1$, $c_3$, and $c_4$ can consistently be obtained from low energy $\pi N$ scattering data). The inclusion of TPE allows one to reduce the short-range cutoff separating long- and short-distance contributions, which helps in reducing the impact of details in the unknown short-distance behavior of the potentials. Nonetheless, we will note in Sec. IV that uncertainties are dominated by this diffuse separation between short and long distances.

There are many practical advantages deriving from a $\chi$EFT that explicitly includes $\Delta$-isobar degrees of freedom, the most immediate one being a numerical consistency between the values of the low-energy constants $c_1$, $c_3$, and $c_4$ inferred from either $\pi N$ or $NN$ scattering. Such a theory also naturally leads to three-nucleon forces induced by TPE with excitation of an intermediate $\Delta$ (the Fujita-Miyazawa three-nucleon force) as well as to two-nucleon electroweak currents (see, for example, Ref. [25]). In addition, there are somewhat strong indications from phenomenology that $\Delta$ isobars play an important role in nuclear structure and reactions. An illustration of this are the three-nucleon forces involving excitation of intermediate $\Delta$ resonances, needed to reproduce the observed energy spectra and level ordering of low-lying states in $s$- and $p$-shell nuclei or the correct spin-orbit splitting of $P$-wave resonances in low-energy $n-\alpha$ scattering (for a review, see Ref. [18]). Another illustration is the relevance of electroweak $N$-to-$\Delta$ transition currents in radiative and weak capture processes involving few-nucleon systems [26], specifically the radiative captures of thermal neutrons on deuteron and $^4$He [27,28] or the weak capture of protons on $^3$He (the so-called hep process) [29]. It is for these reasons that in the present work we construct a minimally nonlocal coordinate space chiral potential, that includes $\Delta$ intermediate states in its TPE component—it is described in detail in Sec. II. Such a coordinate-space representation offers many computational advantages for ab initio calculations of nuclear structure and reactions, in particular for the type of quantum Monte Carlo calculations of $s$- and $p$-shell nuclei very recently reviewed in Ref. [18].

On the experimental side, there are currently about 8000 published $pp$ and $np$ scattering data below pion production threshold corresponding to 24 different scattering observables, including differential cross sections, spin asymmetries, and total cross sections [30,31]; see Ref. [12] for updated assigned $pp$ and $np$ abundance plots in the $(E_{\text{lab}},\theta_{\text{cm}})$ plane. However, not all of these data are mutually compatible and a decision has to be made as to which are more likely to be correct. In principle, the $NN$ scattering amplitude can be determined uniquely, provided a complete set of experiments is given—a rare situation for the case under consideration. Therefore, a theoretical model is needed to provide a smooth energy dependence which allows one to interpolate between different energy values, and helps in deciding on the mutual consistency of nearby data in the $(E_{\text{lab}},\theta_{\text{cm}})$ plane. The PWA carried out in Granada parametrizes [10] the interaction, for internucleon distances $r$ less than 3 fm, in terms of a set equidistant delta shells separated by $\Delta r = 0.6$ fm (in other words, a coarse-grained parametrization), while retaining only the OPE component for $r > 3$ fm. The choice of $\Delta r$ corresponds to the shortest de Broglie wavelength at about pion production threshold, and consequently all the data are weighted with their quoted experimental uncertainty. The result of the analysis was a $3\pi$ self-consistent database comprising a total of 6715 $pp$ and $np$ scattering data. More details on the data analysis specific to our potential are presented in Sec. III. One important aspect of the Granada PWA is the correlation pattern among the fitting parameters, namely different partial waves are mostly

\[ \text{http://www.ugr.es/~amaro/hadronica/}. \]
uncorrelated which, together with the large number of selected data, speaks in favor of a lack of bias in the selection process. Actually the correlation length which decides on the specific form of the potential should be smaller than the distance $\Delta r = 0.6$ fm in the coarse-grained parametrization.

Chiral potentials have been subjected to PWA and confronted to $pp$ and $np$ scattering data up to laboratory energy of 350 MeV. Within the $\chi$EFT framework the Nijmegen group used the TPE potential [24] to carry out $pp$ [6] and $np + pp$ [8] analyses determining the chiral constants $c_3$ and $c_4$ from these data while constraining $c_1$ from $\pi N$ data. Taking the chiral constants from $\pi N$ analyses, Entem and Machleidt [32] used a next-to-next-to-next-to-leading order (N3LO or $Q^3$, $Q$ generically specifying the low momentum scale) chiral potential to fit $pp$ and $np$ scattering data up to laboratory energy of 290 MeV. The resulting $\chi^2$/datum were 1.1 for 2402 $np$ data and 1.50 for 2057 $pp$ data, and consequently a global $\chi^2$/datum of 1.28. The chiral TPE potential [24] was also used within the coarse grained framework to determine the chiral constants in Ref. [11] with a global $\chi^2$/datum of 1.07, based on 6713 $pp$ and $np$ scattering data.

Other available chiral potentials [33,34] have not been confronted to scattering data directly but rather to phase shifts obtained in the Nijmegen analysis (the recent upgrade [35] of Ref. [33] relies on the same procedure, while in Ref. [34] a study of peripheral phase shifts is carried out with two- and three-pion exchange potentials up to order $Q^3$). As we will show in Sec. IV, there is a substantial difference between fitting scattering data and fitting phase shifts mainly because of the existing correlations among the many partial waves and mixing angles. Actually, a good $\chi^2$ fit to phase shifts may yield quite a bad $\chi^2$ in a fit to data. Moreover, the spread in phase-shift values among different high-quality potentials fitting the same data reflects the differences in the potential representation and turns out to be larger than the estimated statistical errors (compare Fig. 1 of Ref. [36] with Fig. 3 of Ref. [37]). The consequences of these larger errors have been discussed in Ref. [38].

The previous comments address the use of chiral potentials to fit selected $NN$ scattering databases which have been obtained from phenomenological representations of the interactions. An obvious question which comes to mind is whether chiral potentials, being credible and general low energy representations of QCD in the $NN$ sector, should be used themselves to select the database. Within the coarse grained framework the impact of chiral interactions on the selection of the database has also been studied in Ref. [11].

The result was that a larger number of data were rejected but at the same time the number of parameters was reduced. This poses the interesting question on what is the meaning of improvement—a particularly critical issue when the potential itself (chiral or not) must be tested against the selected data. Obviously an incorrect model will appear to be correct if a sufficiently large number of data is discarded. However, the theory with just delta shells+$OPE$ is more general than that with delta shells+$OPE+TPE$, and hence data selection based on the former is more reliable. In any case, the results of Ref. [11] show also that the long-range part of the next-to-next-to-leading order (N2LO or $Q^3$) chiral potential can indeed fit the delta shells+$OPE$ selected data satisfactorily with a $\chi^2$/datum of 1.07, when the potential is taken to be valid for internucleon distances ranging from 1.8 fm outwards.

The present paper is organized as follows. In the next section we describe the potential, while in Sec. III we provide a brief discussion of the data fitting. In Sec. IV we report the $\chi^2$ values obtained in the fits as well as the values for the low-energy constants that characterize the potential, and show the calculated phase shifts for the lower partial waves ($S$, $P$, and $D$ waves) and compare them to those from recent PWA’s. There, we also provide tables of the $pp$, $np$, and $nn$ effective range parameters and of deuteron properties, including a figure of the deuteron $S$ and $D$ waves. Finally, in Sec. V we summarize our conclusions. A number of details are relegated to Appendices A–E.

II. POTENTIALS

The two-nucleon potential includes a strong interaction component derived from $\chi$EFT up to next-to-next-to-next-to-leading order (N3LO or $Q^3$) and denoted as $v_{12}$, and an electromagnetic interaction component, including up to terms quadratic in the fine structure constant $\alpha$ (first- and second-order Coulomb, Darwin-Foldy, vacuum polarization, and magnetic moment interactions), and denoted as $v_{12}^{EM}$. The $v_{12}^{EM}$ component is the same as that adopted in the Argonne $v_{18}$ (AV18) potential [5]. The component induced by the strong interaction is separated into long- and short-range parts, labeled, respectively, $v_{12}^{S}$ and $v_{12}^{L}$. The $v_{12}^{S}$ part includes the one pion-exchange (OPE) and two pion-exchange (TPE) contributions, illustrated in Fig. 1. Figure 1(a) represents the OPE contribution at leading order ($LO$ or $Q^0$); Figs. 1(b)–1(g) represent the TPE contributions at next-to-leading order ($NLO$ or $Q^2$) without and with $\Delta$ isobars in the intermediate states; lastly, Figs. 1(h)–1(p) represent subleading TPE contributions at next-to-next-to-leading order ($N2LO$ or $Q^3$). The NLO and N2LO loop corrections contain ultraviolet divergences, which are isolated in dimensional regularization and then reabsorbed into contact interactions by renormalization of the associated low energy constants (LEC’s) [39,40]. Additional loop corrections at NLO and N2LO only lead to renormalization of OPE and contact interactions [39,41], and will not be discussed any further here.

The LO, NLO, and N2LO terms are well known, and explicit expressions for them can be found in Refs. [39,40,42–44]. The LO and NLO terms depend on the pion decay amplitude $F_\pi$, and the nucleon and $N$-to-$\Delta$ axial coupling constants, respectively, $g_A$ and $h_A = 3g_A/\sqrt{2}$ (this value for $h_A$ is from the large $N_c$ expansion or strong-coupling model [45], and is in good agreement with the value inferred from the empirical $\Delta$ width). The subleading N2LO terms also depend on the LEC’s $c_1$, $c_2$, $c_3$, and $c_4$ and the combination of LEC’s $(b_3 + b_8)$, respectively, from the second-order $\pi N$ and $\pi N\Delta$ chiral Lagrangians $\mathcal{L}_N^{\pi N}$ [46] and $\mathcal{L}_\Delta^{\pi N\Delta}$ [43]. The values of these LEC’s, as determined by fits to $\pi N$ scattering data [43], and of the masses and other physical constants adopted in the present study are listed in Tables I and II.

In the static limit, the momentum-space LO, NLO, N2LO terms are functions of the momentum transfer $k$; hereafter,
we define \( k = p' - p \) and \( K = (p' + p)/2 \), where \( p \) and \( p' \) are the initial and final relative momenta of the two nucleons. Coordinate-space expressions for the TPE terms are obtained by using the spectral function representation [44], however, with no spectral cutoff,\(^2\)

\[
v_{L}^{r,TPE}(r) = \frac{1}{2\pi^2} \int_{2m}^{\infty} d\mu \, \mu e^{-\mu r} f^L(\mu) \text{Im}\left[ \hat{v}_{L}^{r,TPE}(O^0 - i\mu) \right],
\]

(2.1)

in terms of the left-cut discontinuity at \( k = 0^+ - i\mu \). Here \( f^L(\mu) = f^L(\mu) = 1, f^T(\mu) = f^T(\mu) = 2/3 \), and \( f^L(\mu) = f^T(\mu) = -(3 + 3\mu r + \mu^2 r^2)/(3 r^2) \), and the functions \( \hat{v}_{L}^{r,TPE}(k) \) are the momentum-space TPE components of the potential at NLO and N2LO,

\[
\hat{v}_{L}^{r,TPE} = \sum_{l=1}^{6} \hat{v}_{L}^{r,TPE}(k) \hat{O}_{l}^{r,T},
\]

(2.2)

with \( \hat{O}_{l}^{r,1} = [1, \sigma_1 \cdot \sigma_2, \sigma_1 \cdot k \sigma_2 \cdot k] \otimes [1, \tau_1 \cdot \tau_2] \) denoted as \( c, t, c, t, c, t, t \). Those corresponding to diagrams (b)–(d) and (h)–(k) in Fig. 1 are known in closed form (see, for example, Ref. [44]) and are listed in Appendix A for completeness; the remaining ones corresponding to diagrams (e)–(g) and (l)–(p) have been derived in terms of a parametric integral, and they too are given in Appendix A. The radial functions \( v_{l}^{r}(r) \) are singular at the origin (they behave as \( 1/r^n \) with \( n \) taking on values up to \( n = 6 \); see Refs. [47,48] for analytical expressions), and each is regularized by a cutoff of the form,

\[
C_{RL}(r) = 1 - \frac{1}{(r/RL)^6 e^{(r-RL)/aL} + 1},
\]

(2.3)

where in the present work three values for the radius \( RL \) are considered \( RL = (0.8,1.0,1.2) \) fm with the diffuseness \( aL \) fixed at \( aL = RL/2 \) in each case. The potential \( v_{L}^{r} \), including the well-known OPE components at LO regularized by the cutoff in Eq. (2.3), then reads in coordinate space,

\[
v_{L}^{r} = \sum_{l=1}^{6} v_{l}^{r}(r) O_{l}^{r} + v_{L}^{r,T}(r) O_{L}^{r,T} + v_{L}^{r,T}(r) O_{L}^{r,T},
\]

(2.4)

where

\[
O_{l}^{r,1} = [1, \sigma_1 \cdot \sigma_2, S_{l2}] \otimes [1, \tau_1 \cdot \tau_2],
\]

(2.5)

\( O_{L}^{T} = \sigma_1 \cdot \sigma_2 T_{12}, \) and \( O_{L}^{T} = S_{l2} T_{12}, \) and \( T_{12} = 3 \tau_1 \cdot \tau_2 - \tau_1 \cdot \tau_2 \) is the isoscalar operator. The terms proportional to \( T_{12} \) account for the charge-independence breaking induced by the difference between the neutral and charged pion masses in the OPE. However, this difference is ignored in the NLO and N2LO loop corrections which have been evaluated with \( m_\pi = (2m_\pi^+ + m_\pi^-)/3 \). Additional (and small) isospin symmetry breaking terms arising from OPE [49] and TPE [50] and from OPE and one-photon exchange [51,52] have also been neglected.

The potential \( v_{L}^{r} \) includes charge-independent (CI) contact interactions at LO, NLO, and N3LO, and charge-dependent (CD) ones at LO and NLO, in momentum-space

\[
\begin{array}{cccccccc}
\text{Table I. Values of (fixed) low energy constants (LEC's):} & \sigma_1 & \sigma_2 & S_{l2} & \tau_1 & \tau_2 \\
\hline\hline
\sigma_1 & \sigma_2 & S_{l2} & \tau_1 & \tau_2 \\
\hline
1.29 & 2.74 & 184.80 & -0.57 & -0.25 & -0.79 & 1.33 & 1.40 \\
\end{array}
\]

\( g_A \) and \( h_A = g_A/\sqrt{2} \) are adimensional, \( F_\pi = 2f_\pi \) is in MeV, and the remaining LEC's are in GeV\(^{-1}\).
\[ v_{12}^S(k, K) = v_{12}^{S, \text{CI}}(k, K) + v_{12}^{S, \text{CD}}(k, K) \]

where \( S_{12}(k) = 3 \sigma_1 \cdot k \sigma_2 \cdot k - k^2 \sigma_1 \cdot \sigma_2, C_S \) and \( C_T \) are the LO LEC’s in standard notation, while \( C_{i=1,...,7} \) and \( D_{i=1,...,15} \) are generally linear combinations of those in the “standard” set, as defined, for example, in Ref. [23]. In the NLO and N3LO contact interactions terms proportional to \( K^2 \) and \( K^4 \), which would lead to \( p^2 \) and \( p^4 \) operators in coordinate space (\( p \rightarrow -i\nabla \) is the relative momentum operator), have been removed by a Fierz rearrangement, for example,

\[ K^m \rightarrow -\frac{1}{2} \sigma_1 \cdot \sigma_2 \frac{k^m}{2m}, \quad (2.8) \]

with \( m = 2 \) or 4. Of course, mixed terms of the type \( k^2 K^2 \) or \( K \times k \) cannot be Fierz-transformed away. In the potential \( v_{12}^{S, \text{CD}}(k, K) \) only terms up to NLO, involving charge-independence breaking (proportional to \( T_{12} \)) and charge-symmetry breaking (proportional to \( r_{1z} + r_{2z} \)), are accounted for. The associated LEC’s, while providing some additional flexibility in the data fitting discussed below (especially \( C_0^{\text{IV}} \) in reproducing the singlet \( nn \) scattering length), are not well constrained.

A couple of comments are now in order. The first is that strict adherence to power counting would require inclusion of additional one-loop as well as two-loop TPE and three-pion exchange contributions at order \( Q^4 \). These contributions have been neglected, because they are known to be small (see, for example, Ref. [23]). Furthermore it is the \( D_i \) LEC’s at \( Q^4 \) that are critical for a good reproduction of phase shifts in lower partial waves, particularly \( D \) waves, and a good fit to the \( NN \) database [23] in the 0–300 MeV range of energies considered in the present study.

The second comment is in reference to isospin symmetry breaking. We have not included explicitly contributions from OPE and one-photon exchange [51,52]. As noted in Ref. [11], this \( \pi-\gamma \) interaction is small and ambiguous, and requires regularization at short distances. So its main effect can be effectively shifted into a counterterm. While this can be improved, we will see below our final fitting results do not seem to require these long-range isospin breaking effects.
III. DATA ANALYSIS

Setting aside electromagnetic (EM) contributions (Coulomb and higher order ones) for the time being, the invariant on-shell scattering amplitude $M$ for the $NN$ system can be expressed in terms of five independent complex functions—the Wolfenstein parametrization—as

$$M(p', p) = a + m \sigma_1 \cdot \hat{n} \sigma_2 \cdot \hat{n} + (g - h) \sigma_1 \cdot \hat{m} \sigma_2 \cdot \hat{m} + (g + h) \sigma_1 \cdot \hat{I} \sigma_2 \cdot \hat{I} + c(\sigma_1 + \sigma_2) \cdot \hat{n},$$

(3.1)

where $\hat{n}$, $\hat{m}$, $\hat{I}$ are three orthonormal vectors along the directions of $p + p'$, $p - p'$, and $p \times p'$, and $p$, $p'$ are the final and initial relative momenta, respectively. The functions $a, m, g, h$, and $c$ are taken to depend on the energy in the laboratory (lab) frame and the scattering angle $\theta$ in the center-of-mass (c.m) frame. Any scattering observable can be constructed out of these amplitudes [30,31].

The $NN$ amplitude is diagonal in pair spin $S$, and pair isospin and isospin projection $T_{MT}$, and is expanded in partial waves as

$$M_{S_L}^{S,T_{MT}}(E, \theta) = \sum_{JLL} i^{L-L'} \sqrt{2L + 1} \left( 1 - \frac{(-1)^{L+S+T}}{2} \right) \times$$

$$\times \langle L(\hat{M}_S - \hat{M}_S') | S_M' | J M_S \rangle \times \langle L0, S_M | J M_S \rangle Y_{L_L}^{M_S-M'_S}(\theta, 0) \times$$

$$\times S_{L_L}^{JJS_T} (p) - \delta_{L_{LL}} \frac{i p}{2},$$

(3.2)

where $L$ and $J$ denote, respectively, the orbital and total angular momenta, the (...) are Clebsch-Gordan coefficients, the $Y_{L_L}^{M_S-M'_S}(\theta, 0)$ are spherical harmonics, the $\delta_{L_{LL}}$ are Kronecker deltas, and the $S_{L_L}^{JJS_T}$ are $S$-matrix elements. Denoting phase shifts as $S_{L_L}^{JJS_T}$, the $S$ matrix is simply given by

$$S_{S_J}^{JJS_T} = e^{i \delta_{L_L}^{JS}},$$

(3.3)

in single channels with $L = L' = J$, and by

$$S_{S_J}^{JJS_T} = \begin{bmatrix} e^{i \delta_{L_L}^{JS}} \cos 2\epsilon_f & i e^{i(L+L'+1)/2} \sin 2\epsilon_f \\ i e^{i(L+L'+1)/2} \sin 2\epsilon_f & e^{i \delta_{L_L}^{JS}} \cos 2\epsilon_f \end{bmatrix},$$

(3.4)

in coupled channels with $S = 1$ and $L, L' = J \mp 1 (\epsilon_f$ is the mixing angle). Hereafter, for notational simplicity we drop from the phase shifts unnecessary subscripts as well as the superscripts $T_{MT}$, with $T = 1$ and $M_T = 1, 0, -1$ for, respectively, $pp$, $np$, and $nn$. The $S$-matrix elements and phase shifts are obtained from solutions of the Schrödinger equation with suitable boundary conditions, as discussed Appendix C. In terms of the amplitudes $M_{S_L}^{S,T_{MT}}$, the functions $a, m, g, h$, and $c$ then read

$$a = (M_{11}^1 + M_{00}^0 + M_{1-1}^1 - M_{-1-1}^1)/4,$$

(3.5)

$$c = i (M_{10}^1 - M_{01}^1 + M_{0-1}^0 - M_{1-1}^1)/(4\sqrt{2}),$$

(3.6)

$$m = (-M_{1-1}^1 + M_{00}^0 + M_{0-1}^0 - M_{-1-1}^1)/4,$$

(3.7)

$$g = (M_{11}^1 + M_{1-1}^1 + M_{11}^0 + M_{1-1}^0 - 2M_{00}^0)/8,$$

(3.8)

$$h = \cos \theta (M_{11}^1 - M_{1-1}^1 - M_{11}^0 + M_{1-1}^0 - 2M_{00}^0)/8 + \sqrt{2} \sin \theta (M_{10}^1 + M_{01}^1 + M_{0-1}^0 - M_{1-1}^0)/8,$$

(3.9)

and this can be further simplified by noting that $M_{01}^0 = -M_{01}^1$, $M_{11}^1 = M_{11}^0$, $M_{1-1}^1 = M_{-1-1}^0$, $M_{10}^1 = -M_{10}^0$, and $M_{11}^1 = M_{11}^0$.

When EM interactions are included, the full scattering amplitudes $M$ are conveniently separated into a part from nuclear interactions and another one stemming from EM interactions,

$$M = M_{EM} + M_N.$$

(3.10)

The $pp$ EM amplitudes contain Coulomb with leading relativistic corrections, vacuum polarization, and magnetic moments contributions, whereas the $np$ ones contain magnetic moment contributions only (see Ref. [10] for a compendium of formulas and references to the original papers; for completeness, however, the determination of the $pp$ phase shifts relative to EM functions and of the $pp$ effective range expansion is summarized in Appendix D). Because of the finite range of the $NN$ force, the nuclear part of the scattering amplitudes $M_N$ converges with a maximum total angular momentum of $J = 15$. In contrast, EM scattering amplitudes $M_{EM}$ require a summation of about a thousand partial waves from the long range and tensor character of the dipolar magnetic interactions. While these corrections are numerically tiny, they are nevertheless indispensable for an accurate description of the data [54].

We use the database developed in Granada and specified in detail in Ref. [10], where a selection of the large collection of $np$ and $pp$ scattering data taken from 1950 until 2013 was made. The adopted criterium was to represent the $NN$ interaction with a general and flexible parametrization, based on a minimal set of theoretical assumptions so as to avoid any systematic bias in the selection process. The aim of the method, first suggested by Gross and Stadler [9], was to obtain a $3\sigma$ self-consistent database. This entails removal of $3\sigma$ outliers and re-fitting iteratively until convergence. The procedure results in a database with important statistical features [12] and therefore amenable to statistical analysis, and leads to the identification of a consistent subset among the large body of 6713 $np$ and $pp$ experimental cross sections and polarization observables. In the present study, in particular, we are concerned with a subset of this $3\sigma$-self-consistent database, namely data below 300-MeV laboratory energy. This database is organized in the following way: There are $N$ sets of data, each one corresponding to a different experiment. Each data set contains measurements at fixed $E_{lab}$ and different scattering angles $\theta$. However a few observables are measured at different $E_{lab}$ and fixed $\theta$, like, for example, total cross sections because their measurement does not involve the scattering angle ($\theta = 0$). An experiment may have a specified systematic error (normalized data), no systematic error (absolute data), or an arbitrarily large systematic error (floated data).
We briefly describe the fitting procedure. The total figure of merit is defined as the usual χ² function,

\[ \chi^2 = \sum_{i=1}^{N} \chi_i^2, \]  

(3.11)

where \( \chi_i^2 \) refers to the corresponding contribution from each data set, which we explain next. In all cases, the \( \chi_i^2 \) for a data set is given by

\[ \chi_i^2 = \sum_{i=1}^{n} \left( \frac{a_i/Z_i - t_i}{\delta a_i/Z_i} \right)^2 + \left( \frac{1 - 1/Z_i}{\delta_{sys}/Z_i} \right)^2, \]  

(3.12)

where \( a_i \) and \( t_i \) are the measured and calculated values of the observable at point \( i \), \( \delta a_i \), and \( \delta_{sys} \) are the statistical and systematic errors, respectively, and \( Z_i \) is a scaling factor chosen to minimize the \( \chi_i^2 \),

\[ Z_i = \left( \sum_{i=1}^{n} \frac{a_i t_i}{\delta a_i^2} + 1 \right) \left( \sum_{i=1}^{n} \frac{t_i^2}{\delta a_i^2} + 1 \right)^{-1}. \]  

(3.13)

The last term in Eq. (3.24) is denoted \( \chi_{sys}^2 \). For absolute data \( Z = 1 \) and \( \chi_{sys}^2 = 0 \), while for float data use of Eq. (3.25) is made with \( \delta_{sys} = \infty \) so that \( \chi_{sys}^2 = 0 \). Normalized data have in most cases \( Z \neq 1 \) such that \( \chi_{sys}^2 \neq 1 \) and the normalization is counted as an extra data point. For some normalized data the systematic error can give a somewhat large \( \chi_{sys}^2 \), because of an underestimation of \( \delta_{sys} \). To account for this, we float data that have \( \chi_{sys}^2 > 9 \) and no extra normalization data is counted. This is in line with the criterion used to build the \( pp \) and \( np \) database. Finally, the total \( \chi^2 \) is the sum of all the \( \chi_i^2 \) for each \( pp \) and \( np \) data set.

The minimization of the objective function \( \chi^2 \) with respect to the LEC’s in Eqs. (2.6) and (2.7) is carried out with the Practical Optimization Using no Derivatives (for Squares), POUNDersS [55]. This derivative-free algorithm is designed for minimizing sums of squares and uses interpolation techniques to construct residuals at each point. In the optimization procedure, we fit first phase shifts and then refine the fit by minimizing the \( \chi^2 \) obtained from a direct comparison with the database. In fact, sizable changes in the total \( \chi^2 \) are found when passing from phase shifts to observables, so this refining is absolutely necessary to claim reasonable fits to data. This is a general feature which is often found, and reflects the different weights in the \( \chi^2 \) contributions of the two different fitting schemes. Indeed, the initial guiding fit to phase shifts chooses a prescribed energy grid arbitrarily, which does not correspond directly to measured energies, nor necessarily samples faithfully the original information provided by the experimental data. Moreover, there are different PWA’s which describe the same data but yield different phase shifts with significantly larger discrepancies than reflected by the inferred statistical uncertainties [10–12].

IV. RESULTS

We report results for the potentials \( v_{12} + v_{12}^{\text{FM}} \) corresponding to three different choices of cutoffs (\( R_1, R_5 \)): model a with (1.2,0.8) fm, model b with (1.0,0.7) fm, and model c with (0.8,0.6) fm. Models a, b, and c were fitted to the Granada database of \( pp \) and \( np \) cross sections, polarization observables, and normalizations up to laboratory energies of 300 MeV, to the \( pp \), \( np \), and \( nn \) singlet scattering lengths, and to the deuteron binding energy. We list the number of \( pp \) and \( np \) data (including normalizations) and corresponding total \( \chi^2 \) for the three models in Table III, where we also report for comparison the \( \chi^2 \) corresponding to the AV18 [5] (of course, without a refit of it) and the same database. The total number of data points changes slightly for each of the various models because of fluctuations in the number of normalizations included in the database according to the criterion discussed at the end of the previous section. In the range (0–300) MeV, the \( \chi^2(pp) \)/datum and \( \chi^2(np) \)/datum are about 1.48, 1.48, 1.52 and 1.20, 1.19, 1.23 for models a, b, and c, respectively; the corresponding global \( \chi^2(pp + np) \)/datum are 1.33, 1.33, 1.37. For the AV18, the \( \chi^2(pp) \)/datum, \( \chi^2(np) \)/datum, and global \( \chi^2(pp + np) \)/datum are 1.84, 1.14, and 1.46, respectively. Note that the global \( \chi^2 \) values above have been evaluated by taking into account the number of fitting parameters characterizing these models (34 in the case of models a, b, and c). Errors for \( pp \) data are significantly smaller than for \( np \), thus explaining the consistently higher \( \chi^2(pp) \)/datum. The quality of the fits deteriorates slightly as the (\( R_1, R_5 \)) cutoffs are reduced from the values (1.2,0.8) fm of model a down to (0.8,0.6) fm of model c.

The fitted values of the LEC’s in Eqs. (2.6) and (2.7) corresponding to models a, b, and c are listed in Table IV. The values for the \( \pi N \) LEC’s in the OPE and TPE terms of these models have already been given in Tables I and II. It is interesting to examine the extent to which these LEC’s satisfy the requirement of naturalness. To this end, following
TABLE IV. Fitted values of the LEC’s corresponding to potential models a, b, and c. The notation \((\pm n)\) means 10\(^{\pm n}\).

</table>

\[ C_S \sim \frac{1}{f_\pi^2} \approx 4.6 \text{ fm}^2, \quad |C_i| \sim \frac{1}{\Lambda_\chi^4 f_\pi^2} \approx 0.18 \text{ fm}^4, \]
\[ |D_i| \sim \frac{1}{\Lambda_\chi^4 f_\pi^2} \approx 0.0070 \text{ fm}^6, \]

(4.1)

where \(f_\pi = 92.4 \text{ MeV}\) and \(\Lambda_\chi = 1 \text{ GeV}\). A glance at Table IV indicates that the LEC’s are generally natural, but for the following exceptions: \(C_5\) in model c, \(C_7\) in models b and c, and \(D_1\), \(D_{10}\), and \(D_{12}\) in all three models considered. As already noted, however, the use of a (momentum-space) Gaussian cutoff mixes orders in the power expansion, because

\[ e^{-R^2/k^2/4} = 1 - \frac{R^2 k^2}{4} + \frac{R^2 k^4}{32} + \cdots \]
\[ T = 0 \, ^3D_3 \] phase and \( \epsilon_1 \) mixing angle, and therefore correlate with the cutoff sensitivity displayed in these cases by models a, b, and c.

The low-energy scattering parameters are listed in Table V, where they are compared to experimental results. The singlet and triplet \( np \), and singlet \( pp \) and \( nn \), scattering lengths are calculated with and without the inclusion of electromagnetic interactions. Without the latter, the effective range function is simply given by 

\[ F(k^2) = k \cot \delta = -1/a + r k^2/2 \]

up to terms linear in \( k^2 \). In the presence of electromagnetic interactions, a more complicated effective range function must be used; it is reported in Appendix D, along with the relevant references.

The latest determinations of the empirical values for the singlet scattering lengths and effective ranges, obtained by retaining only strong interactions (hence the superscript N), are

\[ \begin{align*}
1a_{pp}^N &= -17.3 \pm 0.4 \text{ fm}, & 1r_{pp}^N &= 2.85 \pm 0.04 \text{ fm}, \quad (4.6) \\
1a_{np}^N &= -23.74 \pm 0.02 \text{ fm}, & 1r_{np}^N &= 2.77 \pm 0.05 \text{ fm}, \quad (4.7) \\
1a_{nn}^N &= -18.95 \pm 0.4 \text{ fm}, & 1r_{nn}^N &= 2.75 \pm 0.11 \text{ fm}. \quad (4.8)
\end{align*} \]

FIG. 2. (Color online) \( S \)-wave, \( P \)-wave, and \( D \)-wave phase shifts in the \( np \) \( T = 0 \) channel, obtained in the Nijmegen [3,4], Gross and Stadler [9], and Navarro Pérez et al. [10] partial-wave analyses, are compared to those of models a, b, and c, indicated by the band. For the mixing angle \( \epsilon_1 \) (phase shift \( ^3D_3 \)) the lower limit of the band corresponds to model a (model b) and the upper limit to model c (model c).

FIG. 3. (Color online) Same as in Fig. 2, but for the \( S \)-wave, \( P \)-wave, and \( D \)-wave phase shifts in the \( np \) \( T = 1 \) channel. For the mixing angle \( \epsilon_2 \) the lower limit of the band corresponds to model c and the upper limit to model b.
which imply that charge symmetry and charge independence are broken, respectively, by
\[
\Delta a_{\text{CSB}} = a^N_{pp} - a^N_{nn} = 1.65 \pm 0.60 \text{ fm},
\]
\[
\Delta r_{\text{CSB}} = r^N_{pp} - r^N_{nn} = 0.10 \pm 0.12 \text{ fm},
\]
and
\[
\Delta a_{\text{CIB}} = (a^N_{pp} + a^N_{nn})/2 - a^N_{np} = 5.6 \pm 0.6 \text{ fm},
\]
\[
\Delta r_{\text{CIB}} = (r^N_{pp} + r^N_{nn})/2 - r^N_{np} = 0.03 \pm 0.13 \text{ fm}.
\]

The more significant values for \(\Delta a_{\text{CSB}}\) and \(\Delta a_{\text{CIB}}\) can be compared to those inferred from Table V: \((\Delta a_{\text{CSB}}, \Delta a_{\text{CIB}}) = (2.13, 5.11)\) fm for model a, \((2.34, 5.12)\) fm for model b, and \((1.90, 5.08)\) fm for model c.

In the upper left panel of Fig. 5 we show the \(^3S_0\) phase shifts for \(pp, np,\) and \(nn\) calculated with and without the inclusion of electromagnetic interactions (only model b is considered). There is excellent agreement between these phases and those obtained in the the Granada, Gross and Stadler, and Nijmegen PWA’s, when electromagnetic effects are fully accounted for.

Particularly at low energies (see Fig. 6), the latter provide most of the splitting between the \(pp\) and \(np\) phases, with remaining differences originating from isospin symmetry breaking from the OPE term in \(v_{1}^{S}\), and the central terms in \(v_{1}^{SCD}\), proportional to the LEC’s \(C_{1}^{IT}\) and \(C_{1}^{IV}\) with \(i = 0−2\). In the absence of electromagnetic interactions, the splitting between the \(pp\) and \(nn\) \(^3S_0\) phases is induced by the charge-symmetry breaking terms of \(v_{1}^{SCD}\), proportional to the LEC’s \(C_{1}^{IV}\) with \(i = 0−2\); it is smaller than that between \(pp\) and \(np\) \(^3S_0\) phases.

The effects of isospin symmetry breaking are also seen in the \(pp\) and \(np\) \(^3P_J\) phases with \(J = 0,1,2\) in the upper right and lower panels of Fig. 5 especially at the higher energies. The calculated phases, which correspond again to model b, include electromagnetic effects, but the latter are negligible beyond 100 MeV. The splitting between the \(pp\) and \(np\) \(^3P_J\) phases is mostly from the isotensor and isovector terms of \(v_{1}^{SCD}\), in particular those proportional to the LEC’s \(C_{1}^{IV}\) and \(C_{1}^{TT}\) with \(i = 3\) and 4 associated, respectively, with the tensor and spin-orbit components of \(v_{1}^{SCD}\)—we have already remarked on the unnaturally large values obtained for \(C_{4}^{IV}\) and \(C_{4}^{TT}\) in

---

**TABLE V.** The singlet and triplet np, and singlet pp and nn, scattering lengths and effective ranges corresponding to the three potential models with \((R_1, R_3) = (1.2, 0.8)\) fm (model a), \((1.0, 0.7)\) fm (model b), and \((0.8, 0.6)\) fm (model c).

FIG. 5. (Color online) The $pp$, $np$, and $nn$ $^1S_0$ and the $pp$ and $np$ $^3P_0$, $^3P_1$, and $^3P_2$ phase shifts obtained with potential model b, including the full electromagnetic component.

The fits. There is no evidence on the basis of the Granada and Nijmegen PWA's for such a large splitting, and so the latter is likely to be an artifact of the parametrization adopted for $v_{S,CD}$.

The static deuteron properties are shown in Table VI and compared to experimental values [59–63]. The binding energy $E_d$ is fitted exactly and includes the contributions (about 20 keV) of electromagnetic interactions, among which the largest is that from the magnetic moment term. The asymptotic $S$-state normalization $A_S$, and the $D/S$ ratio $\eta$, are both $\sim 2$ standard deviations from experiment for all models considered. The deuteron (matter) radius $r_d$ is exactly reproduced with model b, but is underpredicted (overpredicted) by about 1.4% (0.7%) with model a (model c). It is should be noted that this observable has negligible contributions from two-body electromagnetic operators [64]. The magnetic moment $\mu_d$, and quadrupole moment $Q_d$, experimental values are underestimated by all three models, but these observables are

FIG. 6. (Color online) The $pp$, $np$, and $nn$ $^1S_0$ up to laboratory energy of 50 MeV including (panel left) and ignoring (panel right) the full electromagnetic component of potential model b.
known to have significant corrections from (isoscalar) two-body terms in nuclear electromagnetic charge and current [64]. Their inclusion would bring the calculated values considerably closer to, if not in agreement with, experiment. Finally, the body terms in nuclear electromagnetic charge and current [64].

In the present study, we have constructed a coordinate-space nucleon-nucleon potential with an electromagnetic interaction component including first- and second-order Coulomb, Darwin-Foldy, vacuum polarization, and magnetic moment terms, and a strong interaction component characterized by long- and short-range parts. The long-range part includes OPE and TPE terms up to N2LO, derived in the static limit from leading and subleading $\pi N$ and $\pi N\Delta$ chiral Lagrangians. Its strength is fully determined by the nucleon and nucleon-to-$\Delta$ axial coupling constants $g_A$ and $h_A$, the pion decay amplitude $F_{\pi}$, and the subleading LEC’s $c_1$, $c_2$, $c_3$, $c_4$, and $b_5 + b_8$, constrained by reproducing $\pi N$ scattering data (the values adopted for all these couplings are listed in Table I). In coordinate space, this long-range part is represented by charge-independent central, spin, and tensor components without and with the isospin dependence $\tau_1 \cdot \tau_2$ (the so-called $v_6$ operator structure), and by charge-dependence-breaking central and tensor components induced by OPE and proportional to the isotor operator $T_{12}$.

The short-range part is described by charge-independent contact interactions specified by a total of 24 LEC’s (two at LO, seven at NLO, and 15 at N3LO) and by charge-dependent ones characterized by 10 LEC’s (two at LO and eight at NLO), five of which multiply charge-symmetry breaking terms proportional to $r_{12} + r_{23}$ and the remaining five multiply charge-dependence breaking terms proportional to $T_{12}$. In the NLO and N3LO contact interactions, Fierz transformations have been used to rearrange terms that in coordinate space would otherwise lead to powers of $\hat{p}$—the relative momentum operator—higher than two. The resulting charge-independent (coordinate-space) potential contains, in addition to the $v_6$ operator structure, spin-orbit $L^2$, quadratic-spin-orbit, and $p^2$ components, while the charge-dependent one retains central, tensor, and spin-orbit components.

The 34 LEC’s in the short-range potential have been constrained by fitting 5291 $pp$ and $np$ scattering data (including normalizations) up to 300 MeV laboratory energies, as assembled in the Granada database, and the $pp$, $np$, and $nn$ scattering lengths, and the deuteron binding energy. The global $\chi^2(pp + np)/datum$ is 1.33 for the three different models we have investigated, each specified by a pair of (coordinate-space) cutoffs, respectively, $R_1$ and $R_2$ for the long- and short-range parts: $(R_1, R_2) = (1.2, 0.8)$ fm for model a, $(1.0, 0.7)$ fm for model b, and $(0.8, 0.6)$ fm for model c. These cutoffs are close to the $1/(2m_n) \sim 0.7$ fm TPE range. The values of the LEC’s corresponding to the three models are given in Table IV. They are generally of natural size, but for a few exceptions, most notably the LEC’s $C_4^{IV}$ and $C_4^{IV}$ multiplying the charge-dependent spin-orbit terms, which lead to relatively large splitting between the $pp$ and $np$ $P_0$ and $P_1$ phase shifts—a splitting that is not consistent with that obtained in both the Nijmegen and Granada PWA’s. It should also be noted that the degree of unnaturalness increases as the short-distance cutoffs are reduced.

Our results suggest that discrepancies between the phases calculated here and those from available PWA’s in some of the partial waves, such as the $\epsilon_1$ mixing angle, could hardly be resolved by carrying out the database selection using the present interaction. We should also note that the renowned Entem and Machleidt N3LO fit up to $E_{lab} = 290$ MeV provides a $\chi^2/datum$ of 1.1 for 2402 $np$ data and 1.5 for 2057 $pp$, and hence a global $\chi^2/datum$ of 1.3. In our case, we describe 2161 (2764) scattering data and 148 (218) normalizations for $pp (np)$, which means that the average contribution to the $\chi^2$
from each additional datum is homogeneous and of order one out of about 800 extra data. So, our fit is as good as the one of Entem and Machleidt with these additional data.

According to our findings the largest uncertainty in the chiral theory when fitting up to a maximum laboratory energy of 300 MeV is provided by the cutoff dependence. Under these circumstances it makes little sense to analyze further PWA's to $pp$ and $np$ scattering data. On the other hand, the reliability of the long distance chiral interaction does not depend on how the short distance unknown interaction is organized. This was proven by the first chiral potential fits by the Nijmegen group from their $pp$ [6] and $np + pp$ [8] analyses and more recently verified with increased statistics by the Granada group [11]. This leaves open the possibility that better fits than those found here should be possible by properly altering the short distance structure. This point has recently been discussed in Ref. [65].

Of course, this cutoff uncertainty could be greatly reduced if the fitting energy range were to be lowered so as to ensure that differences between fitted data and fitting theory fulfill the normality requirement and, at the same time, statistical uncertainties remain at the same level as cutoff uncertainties. Following the recent suggestion [65], we find that this happens if the fitting energy range were to be lowered so as to ensure that better fits than those found here should be possible by comparing data to each additional datum is homogeneous and of order one out of about 800 extra data. So, our fit is as good as the one of Entem and Machleidt with these additional data.

We conclude by observing that, apart from the $p^2$-dependent terms, the potential constructed here has the same operator structure of the AV18, and is of slightly better quality than the AV18 [the AV18 global $\chi^2(pp + np)/datum on the same database up to 300-MeV laboratory energies is 1.46]. It should be fairly straightforward to incorporate it in the few-nucleon calculations based on hyperspherical-harmonics expansion techniques favored by the Pisa group [66], or in the quantum Monte Carlo ones preferred by the ANL/ASU/JLab/LANL collaboration [18]. The Fortran computer program generating the potential will be made available upon request.

ACKNOWLEDGMENTS

We like to thank J. Sarich and S. M. Wild in the Mathematics and Computer Science Division at Argonne National Laboratory for advice on the implementation of POUNDerS in the $\chi^2$-minimization programs. Conversations with F. Gross, J. W. Van Orden, and R. B. Wiringa at various stages of this project are gratefully acknowledged. Finally, we also would like to thank D. Lonardoni and A. Lovato for help on the parallelization of the minimization programs. The work of R.S. is supported by the US Department of Energy, Office of Nuclear Science, under Contract No. DE-AC05-06OR23177. The work of R.N.P., J.E.A., and E.R.A. is supported by the Spanish DGI (Grant No. FIS2011-24149) and Junta de Andalucía (Grant No. FQM225). R.N.P. is also supported by a Mexican CONACYT grant. The calculations were made possible by grants of computing time from the National Energy Research Supercomputer Center (NERSC).

APPENDIX A: COORDINATE-SPACE REPRESENTATION OF THE POTENTIAL $v_{12}^1$

The LO (OPE) terms corresponding to diagram (a) in Fig. 1 are given by

$$v_{12}^{LO}(r) = \frac{Y_0(r) + 2 Y_2(r)}{3}, \quad T_0(r) + 2 T_2(r) \quad (A1)$$

where

$$Y_0(r) = \frac{g_\Lambda^2}{12\pi} \frac{m_{\pi^\pm}^3}{F_\pi^2} e^{-x_\alpha}, \quad T_0(r) = Y_0(r)\left(1 + \frac{3}{x_\alpha} + \frac{3}{x_\alpha^2}\right). \quad (A3) \quad (A4)$$

and $x_\alpha = m_{\pi^\pm} r$. The NLO terms corresponding to diagrams (b)–(d) read [24]

$$v_{12}^{NLO}(r; \Delta) = \frac{1}{8\pi^4 r^4 F_\pi^2} \left[ x \left[ 1 + 10 g_\Lambda^2 - g_\Lambda^4 (23 + 4x^2) \right] K_0(2x) + \left[ 1 + 2g_\Lambda^2 (5 + 2x^2) - g_\Lambda^4 (23 + 12x^2) \right] K_1(2x) \right]. \quad (A5)$$

$$v_{12}^{NLO}(r; \Delta) = \frac{1}{2\pi^4 r^4 F_\pi^2} m_{\pi^\pm} [3x K_0(2x) + (3 + 2x^2) K_1(2x)], \quad (A6)$$

$$v_{12}^{NLO}(r; \Delta) = -\frac{1}{8\pi^4 r^4 F_\pi^2} m_{\pi^\pm} [12x K_0(2x) + (15 + 4x^2) K_1(2x)], \quad (A7)$$

024003-13
where \( x = m_{\pi} r \) (\( m_{\pi} \) is the average pion mass) and \( K_n \) are modified Bessel functions of the second kind. The NLO terms corresponding to diagrams (e) and (f) with a single \( \Delta \) intermediate state are given by

\[
v_{c}^{\text{NLO}}(r; \Delta) = - \frac{1}{6 \pi^2 r^3 y} \frac{g_s^2 h_A^2}{F^2_\pi} e^{-2x} (6 + 12x + 10x^2 + 4x^3 + x^4), \tag{A8}
\]

\[
v_{r}^{\text{NLO}}(r; \Delta) = - \frac{1}{216 \pi^3 r^5} \frac{h_A^2}{F^2_\pi} \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (12x^2 + 5\mu^2 + 12y^2)
- 12y \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (2x^2 + \mu^2 + 2y^2) \arctan \left( \frac{\mu}{2y} \right)
- \frac{1}{216 \pi^3 r^5} \frac{g_s^2 h_A^2}{F^2_\pi} \left[ - 12y \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (2x^2 + \mu^2 + 2y^2) \arctan \left( \frac{\mu}{2y} \right) \right]
+ \frac{6}{y} \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (2x^2 + \mu^2 + 2y^2) \arctan \left( \frac{\mu}{2y} \right), \tag{A9}
\]

\[
v_{\sigma}^{\text{NLO}}(r; \Delta) = - \frac{1}{72 \pi^3 r^5} \frac{g_s^2 h_A^2}{F^2_\pi} \left[ 2 \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2)
- \frac{1}{y} \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2) \arctan \left( \frac{\mu}{2y} \right) \right]. \tag{A10}
\]

\[
v_{\sigma r}^{\text{NLO}}(r; \Delta) = - \frac{1}{54 \pi^3 r^5} \frac{g_s^2 h_A^2}{F^2_\pi} e^{2x} (1 + x) (3 + 3x + x^2), \tag{A11}
\]

\[
v_{\pi}^{\text{NLO}}(r; \Delta) = \frac{1}{144 \pi^3 r^5} \frac{g_s^2 h_A^2}{F^2_\pi} \left[ \frac{1}{2} \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2)
- \frac{1}{y} \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2) \arctan \left( \frac{\mu}{2y} \right) \right]. \tag{A12}
\]

\[
v_{\pi r}^{\text{NLO}}(r; \Delta) = - \frac{1}{54 \pi^3 r^5} \frac{g_s^2 h_A^2}{F^2_\pi} e^{2x} (1 + x) (3 + 3x + x^2), \tag{A13}
\]

where \( y = \Delta M r \) (\( \Delta M \) is the \( \Delta \)-nucleon mass difference) and the parametric integral over \( \mu \) is carried out numerically. The NLO terms corresponding to diagram (g) with 2 \( \Delta \) intermediate states are

\[
v_{c}^{\text{NLO}}(r; 2\Delta) = - \frac{1}{108 \pi^3 r^5} \frac{h_A^4}{F^2_\pi} \left[ \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} \left[ 4y^2 + 2(2x^2 + \mu^2 + 2y^2)^2 \sqrt{\mu^2 + 4x^2} \right] \right]
+ \frac{1}{y} \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (2x^2 + \mu^2 + 2y^2)(2x^2 + \mu^2 + 6y^2) \arctan \left( \frac{\mu}{2y} \right) \right], \tag{A14}
\]

\[
v_{r}^{\text{NLO}}(r; 2\Delta) = - \frac{1}{1944 \pi^3 r^5} \frac{h_A^4}{F^2_\pi} \left[ \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (24x^2 + 11\mu^2 + 24y^2) + 6(2x^2 + \mu^2 + 2y^2)^2 \right]
- \frac{3}{y} \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (2x^2 + \mu^2 + 2y^2)(2x^2 + \mu^2 + 10y^2) \arctan \left( \frac{\mu}{2y} \right) \right], \tag{A15}
\]

\[
v_{\sigma}^{\text{NLO}}(r; 2\Delta) = - \frac{1}{1296 \pi^3 r^5} \frac{h_A^4}{F^2_\pi} \left[ - 6 \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2)
+ \frac{1}{y} \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2) \arctan \left( \frac{\mu}{2y} \right) \right], \tag{A16}
\]

\[
v_{\sigma r}^{\text{NLO}}(r; 2\Delta) = - \frac{1}{7776 \pi^3 r^5} \frac{h_A^4}{F^2_\pi} \left[ - 2 \int_0^\infty d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2)
+ \frac{1}{y} \int_0^\infty d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2) \arctan \left( \frac{\mu}{2y} \right) \right], \tag{A17}
\]
\[ v_{NN}^{\text{NLO}}(r; 2\Delta) = \frac{1}{2592\pi r^5 F_{\pi}^4} \left[ -6 \int_{0}^{\infty} d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2) 
\right. \\
+ \frac{1}{y} \int_{0}^{\infty} d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2)(\mu^2 + 12y^2) \arctan \frac{\mu}{2y} \right], \tag{A18} \\
\]

\[ v_{\sigma N}^{\text{NLO}}(r; 2\Delta) = \frac{1}{15552\pi r^3 F_{\pi}^4} \left[ -2 \int_{0}^{\infty} d\mu \frac{\mu^2}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2) 
\right. \\
+ \frac{1}{y} \int_{0}^{\infty} d\mu \frac{\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2)(-\mu^2 + 4y^2) \arctan \frac{\mu}{2y} \right]. \tag{A19} \\
\]

Moving on to the loop corrections at N2LO, the terms corresponding to diagrams (h)–(k) are given by

\[ v_{c}^{\text{N2LO}}(r; \Delta) = \frac{3}{2\pi^2 F_{\pi}^6} g_{\pi}^2 e^{-2x} [2c_1 x^2 (1 + x)^2 + c_2 (6 + 12x + 10x^2 + 4x^3 + 4x^4)], \tag{A20} \\
\]

\[ v_{\sigma r}^{\text{N2LO}}(r; \Delta) = \frac{1}{3\pi^2 F_{\pi}^6} g_{\pi}^2 c_4 e^{-2x} (1 + x)(3 + 3x + 2x^2), \tag{A21} \\
\]

\[ v_{\tau r}^{\text{N2LO}}(r; \Delta) = - \frac{1}{3\pi^2 F_{\pi}^6} g_{\pi}^2 c_4 e^{-2x} (1 + x) (3 + 3x + x^2), \tag{A22} \\
\]

while those corresponding to diagrams (l)–(o) are given by

\[ v_{c}^{\text{N2LO}}(r; \Delta) = \frac{1}{18\pi^3 F_{\pi}^6} \left[ \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} [-24c_1 x^2 + c_2 (5\mu^2 + 12x^2 + 12y^2) - 6c_3 (\mu^2 + 2x^2)] 
\right. \\
+ \frac{6}{y} \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 2x^2 + 2y^2) [4c_1 x^2 - 2c_2 y^2 + c_3 (\mu^2 + 2x^2)] \arctan \frac{\mu}{2y} \right], \tag{A23} \\
\]

\[ v_{\tau r}^{\text{N2LO}}(r; \Delta) = - \frac{1}{54\pi^3 F_{\pi}^6} \left[ \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 2x^2 + 2y^2) \arctan \frac{\mu}{2y} \right] \\
- \frac{1}{54\pi^3 F_{\pi}^6} \left[ \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + x^2 + 2y^2) \right. \\
+ \frac{6}{y} \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 2x^2 + 2y^2)^2 \arctan \frac{\mu}{2y} \right], \tag{A24} \\
\]

\[ v_{\sigma}^{\text{N2LO}}(r; \Delta) = \frac{1}{18\pi^3 F_{\pi}^6} \left[ \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2) 
\right. \\
- \frac{1}{y} \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2)(\mu^2 + 4y^2) \arctan \frac{\mu}{2y} \right], \tag{A25} \\
\]

\[ v_{\sigma r}^{\text{N2LO}}(r; \Delta) = \frac{1}{108\pi^3 F_{\pi}^6} \left[ \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2) 
\right. \\
- \frac{1}{y} \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (\mu^2 + 4x^2)(\mu^2 + 4y^2) \arctan \frac{\mu}{2y} \right], \tag{A26} \\
\]

\[ v_{\tau r}^{\text{N2LO}}(r; \Delta) = \frac{1}{36\pi^3 F_{\pi}^6} \left[ \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2) 
\right. \\
- \frac{1}{y} \int_{0}^{\infty} \frac{d\mu}{\sqrt{\mu^2 + 4x^2}} e^{-\sqrt{\mu^2 + 4x^2}} (3 + 3\sqrt{\mu^2 + 4x^2} + \mu^2 + 4x^2)(\mu^2 + 4y^2) \arctan \frac{\mu}{2y} \right]. \tag{A27} \\
\]
\[ v_{ir}^{N2LO}(r; \Delta) = \frac{1}{216 \pi^3 r^6} \frac{c_4}{F_4^2} \left[ 2 \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (3 + 3 \sqrt{\mu^2 + 4 x^2} + \mu^2 + 4 x^2) \right. \\
- \frac{1}{y} \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (3 + 3 \sqrt{\mu^2 + 4 x^2} + \mu^2 + 4 x^2) (\mu^2 + 4 y^2) \arctan \frac{\mu}{2 y} \right]. \] (A28)

Lastly, the contributions corresponding to diagram (p) read

\[ v_{c}^{N2LO}(r; 2\Delta) = - \frac{2}{81 \pi^3 r^6} \frac{(b_3 + b_8) h_A^3}{F_2^4} \left[ \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} [6 (\mu^2 + 2 x^2 + 2 y^2)^2 / \mu^2 + 4 y^2] + 11 \mu^2 + 24 x^2 + 12 y^2 \right] \\
- \frac{3}{y} \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (\mu^2 + 2 x^2 + 10 y^2) (\mu^2 + 2 x^2 + 2 y^2) \arctan \frac{\mu}{2 y} \right]. \] (A29)

\[ v_{\sigma}^{N2LO}(r; 2\Delta) = - \frac{1}{128 \pi^3 r^6} \frac{(b_3 + b_8) h_A^3}{F_2^4} \left[ -6 \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (\mu^2 + 2 x^2 + 10 y^2) (\mu^2 + 2 x^2 + 2 y^2) \arctan \frac{\mu}{2 y} \right]. \] (A31)

\[ v_{\sigma r}^{N2LO}(r; 2\Delta) = - \frac{1}{972 \pi^3 r^6} \frac{(b_3 + b_8) h_A^3}{F_2^4} \left[ -6 \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (\mu^2 + 2 x^2 + 10 y^2) (\mu^2 + 2 x^2 + 2 y^2) \arctan \frac{\mu}{2 y} \right]. \] (A32)

\[ v_{l}^{N2LO}(r; 2\Delta) = \frac{1}{324 \pi^3 r^6} \frac{(b_3 + b_8) h_A^3}{F_2^4} \left[ -6 \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (3 + 3 \sqrt{\mu^2 + 4 x^2} + \mu^2 + 4 x^2) \right. \\
+ \frac{1}{y} \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (3 + 3 \sqrt{\mu^2 + 4 x^2} + \mu^2 + 4 x^2) (\mu^2 + 12 y^2) \arctan \frac{\mu}{2 y} \right]. \] (A33)

\[ v_{tr}^{N2LO}(r; 2\Delta) = \frac{1}{1944 \pi^3 r^6} \frac{(b_3 + b_8) h_A^3}{F_2^4} \left[ -6 \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (3 + 3 \sqrt{\mu^2 + 4 x^2} + \mu^2 + 4 x^2) \right. \\
+ \frac{1}{y} \int_0^\infty \mu^2 \sqrt{\mu^2 + 4 x^2} e^{-\mu^2 + 4 x^2} (3 + 3 \sqrt{\mu^2 + 4 x^2} + \mu^2 + 4 x^2) (\mu^2 + 12 y^2) \arctan \frac{\mu}{2 y} \right]. \] (A34)

The radial functions of the charge-independent part of the potential \( v_{12}^c \) in Eq. (2.4) are defined as

\[ v_{12}^c(r) = v_{c}^{NLO}(r; \Delta) + v_{c}^{N2LO}(r; 2\Delta) + v_{c}^{N2LO}(r; \Delta) + v_{c}^{N2LO}(r; 2\Delta), \] (A35)

\[ v_{12}^r(r) = v_{r}^{NLO}(r; \Delta) + v_{r}^{NLO}(r; 2\Delta) + v_{r}^{N2LO}(r; \Delta) + v_{r}^{N2LO}(r; 2\Delta), \] (A36)

\[ v_{12}^T(r) = v_{r}^{LO}(r) + v_{c}^{NLO}(r; \Delta) + v_{c}^{N2LO}(r; \Delta) + v_{c}^{N2LO}(r; 2\Delta), \] (A37)

\[ v_{12}^{\sigma T}(r) = v_{\sigma r}^{LO}(r) + v_{c}^{NLO}(r; \Delta) + v_{c}^{N2LO}(r; \Delta) + v_{c}^{N2LO}(r; 2\Delta), \] (A38)

\[ v_{12}^{\sigma r}(r) = v_{r}^{LO}(r) + v_{r}^{NLO}(r; \Delta) + v_{r}^{NLO}(r; 2\Delta) + v_{r}^{N2LO}(r; \Delta) + v_{r}^{N2LO}(r; 2\Delta), \] (A39)

while those of its charge-dependent part are defined as

\[ v_{12}^{\sigma T}(r) = \frac{Y_0(r) - Y_1(r)}{3}, \] (A41)

\[ v_{12}^{\sigma r}(r) = \frac{T_0(r) - T_1(r)}{3}. \] (A42)
Each is multiplied by the cutoff $C_{R_s}(r)$,

$$v_i^l(r) \rightarrow C_{R_s}(r) v_i^l(r),$$

with $l = c, t, \sigma, \tau, t, t, \sigma, T, t T$.

**APPENDIX B: COORDINATE-SPACE REPRESENTATION OF THE POTENTIAL $v^S_{12}$**

The coordinate-space representation of a (regularized) term $O(K, k)$ in Eqs. (2.6) and (2.7) follows from

$$O(r) = \int \frac{dk}{(2\pi)^3} \int \frac{dK}{(2\pi)^3} e^{i \mathbf{k} \cdot (\mathbf{r} - \mathbf{r}')} O(\mathbf{K}, \mathbf{k}) e^{i \mathbf{K} \cdot \mathbf{r}'},$$

where $\mathbf{r}$ is the relative position and $\mathbf{K} \rightarrow \mathbf{p} = -i \nabla \delta(\mathbf{r}' - \mathbf{r})$, the relative momentum operator. For the momentum-space operator structures present in Eqs. (2.6) and (2.7) one finds

$$\begin{align*}
1 & \rightarrow C_{R_s}(r), \\
k^2 & \rightarrow -C_{R_s}(r) - \frac{2}{r} C_{R_s}^{(1)}(r), \\
k^4 & \rightarrow C_{R_s}^{(4)}(r) + \frac{4}{r} C_{R_s}^{(3)}(r), \\
S_{12}(k) & \rightarrow - \left[ C_{R_s}^{(2)}(r) - \frac{1}{r} C_{R_s}^{(1)}(r) \right] S_{12}, \\
i \mathbf{S} \cdot (\mathbf{K} \times \mathbf{k}) & \rightarrow - \frac{1}{r} C_{R_s}^{(1)}(r) \mathbf{L} \cdot \mathbf{S}, \\
\mathbf{K}^2 & \rightarrow \left\{ \mathbf{p}^2, C_{R_s}(r) \right\}, \\
(\mathbf{K} \times \mathbf{k})^2 & \rightarrow - \frac{1}{r^2} \left[ C_{R_s}^{(2)}(r) - \frac{1}{r} C_{R_s}^{(1)}(r) \right] \mathbf{L}^2 - \left\{ \mathbf{p}^2, \frac{1}{r} C_{R_s}(r) \right\} - \frac{1}{r} C_{R_s}^{(3)}(r), \\
[S \cdot \mathbf{(K} \times \mathbf{k})]^2 & \rightarrow - \frac{1}{r^2} \left[ C_{R_s}^{(2)}(r) - \frac{1}{r} C_{R_s}^{(1)}(r) \right] (\mathbf{L} \cdot \mathbf{S})^2 - \left\{ \mathbf{p}^2 (1 + \sigma_1 \cdot \sigma_2) - \sigma_1 \cdot \mathbf{p} \sigma_2 \cdot \mathbf{p}, \frac{1}{r} C_{R_s}^{(1)}(r) \right\},
\end{align*}$$

where

$$C_{R_s}^{(n)}(r) = \frac{d^n C_{R_s}(r)}{dr^n}.$$
\[ v_{s}^{\text{bb}}(r) = -D_{s} \frac{1}{r^3} \left[ C_{R_{s}}^{(2)}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\text{q}}(r) = -D_{10} \frac{1}{r^2} \left[ C_{R_{s}}^{(2)}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\text{qq}}(r) = -D_{11} \frac{1}{r^2} \left[ C_{R_{s}}^{(2)}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{p}(r) = D_{12} \left[ -C_{R_{s}}^{(2)}(r) - \frac{2}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\mu}(r) = D_{13} \left[ -C_{R_{s}}^{(2)}(r) - \frac{2}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\nu}(r) = D_{14} \left[ C_{R_{s}}^{(2)}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\rho}(r) = D_{15} \left[ C_{R_{s}}^{(2)}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{T}(r) = C_{0}^{\text{IT}} C_{R_{s}}(r) + C_{1}^{\text{IT}} \left[ -C_{R_{s}}^{(2)}(r) - \frac{2}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\tau}(r) = C_{0}^{\text{IV}} C_{R_{s}}(r) + C_{1}^{\text{IV}} \left[ -C_{R_{s}}^{(2)}(r) - \frac{2}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\tau}(r) = C_{2}^{\text{IT}} \left[ -C_{R_{s}}^{(2)}(r) - \frac{2}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{\tau}(r) = C_{2}^{\text{IV}} \left[ -C_{R_{s}}^{(2)}(r) - \frac{2}{r} C_{R_{s}}^{(1)}(r) \right], \]  
\[ v_{s}^{T}(r) = -C_{3}^{\text{IT}} C_{R_{s}}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r), \]  
\[ v_{s}^{T}(r) = -C_{3}^{\text{IV}} C_{R_{s}}(r) - \frac{1}{r} C_{R_{s}}^{(1)}(r), \]  
\[ v_{s}^{\tau T}(r) = -C_{4}^{\text{IT}} C_{R_{s}}^{(1)}(r), \]  
\[ v_{s}^{\tau T}(r) = -C_{4}^{\text{IV}} C_{R_{s}}^{(1)}(r). \]  

Note that in Eqs. (B8) and (B9) only the terms proportional to \( L^2 \) and \( (L \cdot S)^2 \) are retained.

**APPENDIX C: SOLUTION OF THE SCHRÖDINGER EQUATION WITH \( v_{12} \)**

In this Appendix, we discuss the solution of the Schrödinger equation with \( v_{12} \), which contains \( p^2 \)-dependent central and tensor terms. For simplicity, we ignore the electromagnetic and charge-dependent parts of \( v_{12} \)—the treatment in the presence of \( v_{\text{EM}}^{\text{c}} \) is discussed in the following appendix. In spin \( S \) and isospin \( T \) channel, the potential reads

\[ v_{12}^{TS} = v_{T}^{c}(r) + v_{T}^{p}(r) S_{12} + v_{T}^{q}(r) L \cdot S + v_{T}^{q}(r) L^2 + v_{T}^{\mu}(r)(L \cdot S)^2 + \left[ v_{T}^{\mu}(r) + v_{T}^{\mu}(r) S_{12} \right] \cdot \mathbf{p}^2, \]  
with

\[ \mathbf{p}^2 = \frac{L^2}{r^2} - \frac{2}{r} \frac{d}{dr} \frac{d^2}{dr^2}. \]  

For single channels \(( J = L \), where \( L \) and \( J \) are the orbital and total angular momenta\), the Schrödinger equation for the reduced radial function \( u_{T,S,J}(r) \) reads

\[-(1 + \tau)u'' - \tau' u' + \left[ v - \frac{\mathbf{p}^2}{2} - k^2 \right] u = 0, \]  

\[ 024003-18 \]
where

\[ v_{T SJ} = 2 \mu \left[ v_{T S}^q + \delta_{S1}(2v_T^q - v_T^q) + J(J + 1) \left( v_{T S}^q + 2v_T^p - \frac{2v_T^p}{r^2} + \delta_{S1} \frac{4v_T^p}{r^2} \right) + \delta_{S1} v_T^b \right] + \frac{J(J + 1)}{r^2}, \]  

(C4)

\[ \overline{v}_{T SJ} = 4 \mu \left( v_{T S}^p + \delta_{S1} 2v_T^{p*} \right), \]  

(C5)

\( \mu \) is the reduced mass, and the subscripts have been dropped for brevity. The dependence on the first derivative \( u' \) is removed by setting

\[ u = \lambda w, \]  

(C6)

and by requiring that terms proportional to \( u' \) vanish. One finds that \( \lambda \) must satisfy

\[ 2(1 + \overline{v})\lambda + \overline{v}\lambda = 0, \]  

(C7)

which has the solution,

\[ \lambda = (1 + \overline{v})^{-1/2}. \]  

(C8)

The function \( w \) then satisfies

\[ w'' = f w, \quad (1 + \overline{v})f = v - \frac{(\overline{v}^2/2)^2}{1 + \overline{v}^2} - k^2, \]  

(C9)

with the boundary condition (reinstating the appropriate superscripts and subscripts for the case under consideration),

\[ \frac{w_{T SJ}(r)}{r} \simeq \frac{1}{2} \left[ h_j^{(2)}(kr) + S_{jj}^{ST}(k) h_j^{(1)}(kr) \right], \]  

(C10)

where the Hankel functions are defined as \( h_j^{(1,2)}(kr) = j_j(kr) \pm i n_j(kr) \), \( j_j(kr) \) and \( n_j(kr) \) being the regular and irregular spherical Bessel functions, respectively. The differential equation above is solved with the standard Numerov method.

In coupled channels \((L = J \pm 1)\) it is convenient to introduce the \( 2 \times 2 \) matrices \( V \) and \( \overline{V} \) with matrix elements given, respectively, by

\[ v_{T SJ}^+ = 2 \mu \left[ v_{T 1}^q - \frac{J - 1}{2J + 1} v_T^q + (J - 1)v_T^p + J(J + 1) \left( v_{T 1}^q + 2v_T^p - \frac{4J - 2}{2J + 1} \frac{v_T^p}{r^2} \right) + (J - 1)^2 v_T^b \right] + \frac{J(J - 1)}{r^2}, \]  

(C11)

\[ v_{T SJ}^- = 2 \mu \left[ v_{T 1}^q - \frac{J + 2}{2J + 1} v_T^q - (J + 2)v_T^p + (J+1)(J+2) \left( v_{T 1}^q + 2v_T^p - \frac{4J + 2}{2J + 1} \frac{v_T^p}{r^2} \right) + (J + 2)^2 v_T^b \right] + \frac{(J+1)(J+2)}{r^2}, \]  

(C12)

\[ v_{T SJ}^J = \frac{\sqrt{J(J+1)}}{2J + 1} \left( v_T^q + 2 \frac{J^2 + J + 1}{r^2} v_T^p \right), \]  

(C13)

\[ v_{T SJ}^J = v_{T SJ}^- = v_{T SJ}^+, \]  

(C14)

and

\[ \overline{v}_{T SJ}^+ = 4 \mu \left( v_{T 1}^p - \frac{J - 1}{2J + 1} v_T^{p*} \right), \]  

(C15)

\[ \overline{v}_{T SJ}^- = 4 \mu \left( v_{T 1}^p - \frac{J + 2}{2J + 1} v_T^{p*} \right), \]  

(C16)

\[ \overline{V}_{T SJ}^J = 24 \mu \frac{\sqrt{J(J+1)}}{2J + 1} v_T^{p*}, \quad \overline{V}_{T SJ}^J = \overline{v}_{T SJ}^J, \]  

where the subscript \(-\) or \(+\) specifies the orbital angular momentum \( L = J - 1 \) or \( L = J + 1 \). With these definitions, the coupled-channel Schrödinger equation can be written as

\[ -(1 + \overline{V})U'' - \overline{V}'U' + \left[ V - \frac{\overline{V}''}{2} - k^2 \right] U = 0, \]  

(C17)

where the transpose of the \( U \) vector is given by \( U^T = (u_{-+},u_{++}) \) or \( U^T = (u_{-+},u_{++}) \), depending on whether the incoming wave has \( L = J - 1 \) or \( L = J + 1 \). Introducing the \( 2 \times 2 \) matrix \( \Lambda \) with

\[ U = \Lambda W, \]  

(C18)
and requiring that terms proportional to $W'$ vanish lead to
\[
2(1 + \nabla)\Lambda' + \nabla' \Lambda = 0.
\] (C19)

The set of first-order differential equations above is solved with the Runge-Kutta method by integrating out $\longrightarrow$ in. Note that in the limit $r \to \infty$, $\Lambda$ reduces to the identity matrix (and hence the asymptotic behavior of $w_\pm$ is the same as that of $u_\pm$).

Straightforward manipulations allow one to cast the Schrödinger equation for $W$ in the standard form,
\[
W'' = F W, \quad (1 + \nabla)\Lambda F^{-1} = V - \frac{1}{4} \nabla'(1 + \nabla)^{-1} \nabla' - k^2,
\] (C20)

with the boundary conditions (again, reinstating superscripts and subscripts),
\[
\frac{w_{TS}^L(r)}{r} \approx \frac{1}{2} \left[ \delta_{L/L} h_L^{(2)}(kr) + S_{L/L}^{ST}(k) h_L^{(1)}(kr) \right],
\] (C21)

where $L = J \mp 1$ is the orbital angular momentum of the incoming wave.

**APPENDIX D: pp PHASE SHIFTS AND EFFECTIVE RANGE EXPANSION**

We discuss briefly the calculation of the $pp$ phase shifts and effective range expansion with inclusion of the full electromagnetic potential $v_{\text{EM}}^{12}$ [5]. Radial wave functions behave in the asymptotic region ($r \gtrsim 30$ fm) as
\[
\mu_L(r) = \frac{1}{2} \left[ \tilde{h}_L^{(2)}(kr; \eta') + e^{2i\delta_L^{\text{EM}}(kr; \eta')} \tilde{h}_L^{(1)}(kr; \eta') \right],
\] (D1)

where $L = J$ for single channels or $L = L' = J \mp 1$ for coupled channels (the pair isospin and spin subscripts $T$ and $S$ have been dropped for simplicity), $\tilde{h}_L^{(1,2)}(kr; \eta')$ are defined in terms of regular, $\tilde{F}_L(kr; \eta')$, and irregular, $\tilde{G}_L(kr; \eta')$, electromagnetic (EM) functions as
\[
\tilde{h}_L^{(1,2)}(kr) = \frac{\tilde{F}_L(kr; \eta')}{kr} \mp i \frac{\tilde{G}_L(kr; \eta')}{kr},
\] (D2)

$\delta_L^{\text{EM}}$ are the EM phase shifts shown in Sec. IV, and the Coulomb parameter $\eta'$ is defined [67] as
\[
\eta' = \frac{\alpha M_p}{2k} \frac{1 + 2k^2/M_p^2}{\sqrt{1 + k^2/M_p^2}}.
\] (D3)

The EM functions, generically denoted as $X_L(kr; \eta')$, are solutions of the radial equation,
\[
\left[ \frac{d^2}{dr^2} + k^2 - \frac{L(L + 1)}{r^2} - M_p[V_{C1}(r) + V_{C2}(r)] + V_{VP}(r) \right] X_L(kr; \eta') = 0,
\] (D4)

where $V_{C1}(V_{C2})$ and $V_{VP}$ are, respectively, the first-order (second-order) Coulomb and vacuum polarization terms. These terms include form factors to remove singularities in the $r = 0$ limit [5]. Note that the Darwin-Foldy and magnetic moment corrections are not included above because at large $r$ the former falls off exponentially and the latter behaves as $1/r^3$.

Following Ref. [68] and treating the $V_{C2}(r)$ and $V_{VP}(r)$ corrections in first-order perturbation theory, one finds that

FIG. 9. (Color online) Central components of the long-range potential $v^L_{12}$ in pair spin-isospin channels $ST = 00$ and 11.

FIG. 10. (Color online) Same as in Fig. 9, but for the short-range charge-independent potential $v^{SCi}_{12}$.

FIG. 11. (Color online) Same as in Fig. 9 but in pair spin-isospin channels $ST = 01$ and 10.
FIG. 12. (Color online) Same as in Fig. 10 but in pair spin-isospin channels $ST = 01$ and 10.

FIG. 13. (Color online) Tensor components of the long-range potential $v_L^{12}$ in pair isospin channels $T = 0$ and 1.

FIG. 14. (Color online) Same as in Fig. 13 but for the short-range charge-independent potential $v_S^{12,CI}$. 
where the $F_L$ and $G_L$ are standard Coulomb functions, the function $V(r)$ is proportional to $V_{C2}(r)$ and $V_{VP}(r)$,

$$V(r) = \frac{M_p}{k} [V_{C2}(r) + V_{VP}(r)], \quad (D7)$$

and the phase shifts $\rho_L$ and $\tau_L$ corresponding, respectively, to $V_{C2}$ and $V_{VP}$ are given (in first-order perturbation theory) by

$$\tan(\rho_L + \tau_L) \simeq \rho_L + \tau_L = -\int_0^{\infty} dr F_L(kr; \eta') V(r) F_L(kr; \eta'). \quad (D8)$$

In the absence of $V_{C2}$ and $V_{VP}$, the solutions $\overline{F}_L$ and $\overline{G}_L$ reduce to the regular and irregular Coulomb functions. In the computer programs Eqs. (D5)–(D6) are used to construct the EM functions and Eq. (D8) to obtain the phase shifts $\rho_L$ and $\tau_L$.

The effective range expansion in the $^3S_0$ channel is obtained as [67–69]

$$F_{EM}(k^2) = -\frac{1}{a_{EM}} + \frac{1}{2} r_{EM} k^2 + \cdots, \quad (D9)$$

with

$$F_{EM}(k^2) = k C_0^2(\eta') \left(1 + x_0\right) \cot \delta_{EM} - \tan \tau_0 \frac{1}{1 + A_1(1 - x_0)}$$

$$+ 2 k \eta' h(\eta') (1 - A_2) + k^2 d [C_0^2(\eta') - 1] + k \tilde{\tau}_0, \quad (D10)$$

where

$$C_0^2(\eta') = \frac{2\pi \eta'}{e^{2\pi \eta'} - 1}, \quad (D11)$$

$$h(\eta') = -\gamma - \ln \eta' + \sum_{n=1}^{\infty} \frac{\eta'^2}{n(n^2 + \eta'^2)},$$

$$x_0 = -\frac{4\alpha}{3\pi} \eta' \int_0^{\infty} dr \frac{I(r)}{r} F_0(kr; \eta') G_0(kr; \eta'),$$

$$\tilde{\tau}_0 = -\frac{4\alpha}{3\pi} \eta' \int_0^{\infty} dr \frac{I(r)}{r} [C_0^2(\eta') G_0^2(kr; \eta') - 1], \quad (D12)$$

$$d = \frac{\alpha}{M_p},$$

$$A_1 = 4 d k \eta'[\ln(2 d k \eta') + h(\eta') + 2 \gamma - 1], \quad (D13)$$

$$A_2 = 2 d k \eta'(2 \ln \alpha + 2 \gamma - 1) + \frac{A_1}{2},$$

$\gamma$ is Euler’s constant, and the function $I(r)$ entering the vacuum polarization potential $V_{VP}(r)$ is defined as in Ref. [68],

$$I(r) = \int_1^{\infty} dx e^{2m_0 x r} \left(1 + \frac{1}{2 x^2}\right) \frac{\sqrt{x^2 - 1}}{x^2}. \quad (D14)$$

The effective range function $F_{EM}(k^2)$ corresponding to model b is shown in Fig. 8. The numerical methods are stable down to laboratory energies of 1 keV.
APPENDIX E: TABLES OF PHASE SHIFTS AND FIGURES OF POTENTIAL COMPONENTS

The \(pp\) and \(np\) phase shifts calculated with model b are listed in Tables VII–IX, while the various components of the long-range \(v^{L}_{12}\) and short-range \(v^{S,CI}_{12}\) potentials corresponding to models a, b, and c and projected out in pair spin and isospin \(S = 0, 1\) and \(T = 0, 1\), are shown in Figs. 9–19.

FIG. 17. (Color online) Quadratic orbital angular momentum components of the short-range charge-independent potential \(v^{S,CI}_{12}\) in pair spin channels \(S = 0, 1\).

FIG. 18. (Color online) Quadratic relative momentum components of the short-range charge-independent potential \(v^{S,CI}_{12}\) in pair spin channels \(S = 0, 1\).

FIG. 19. (Color online) Quadratic-relative-momentum-tensor components of the short-range charge-independent potential \(v^{S,CI}_{12}\) in pair isospin channels \(T = 0, 1\).
